

Package **mathfont** v. 2.4a Implementation

Conrad Kosowsky

June 2025

kosowsky.latex@gmail.com

For easy, off-the-shelf use, type the following in your preamble and compile with X^ET_EX or L^aU_TE_X:

```
\usepackage[⟨font name⟩]{mathfont}
```

As of version 2.0, using L^aU_TE_X is recommended.

Overview

The **mathfont** package adapts unicode text fonts for math mode. The package allows the user to specify a default unicode font for different classes of math symbols, and it provides tools to change the font locally for math alphabet characters. When typesetting with L^aU_TE_X, **mathfont** adds resizable delimiters, big operators, and a MathConstants table to text fonts.

This file documents the code for the **mathfont** package. It is not a user guide! If you are looking for instructions on how to use **mathfont** in your document, see **mathfont-user-guide.pdf**, which is included with the **mathfont** installation and is available on CTAN. See also the other **pdf** documentation files for **mathfont**. Section 1 of this document begins with the implementation basics, including package declaration and package options. Section 2 deals with errors and messaging, and section 3 provides package default settings. Section 4 contains fontloader, and section 5 contains the optional-argument parser for `\mathfont`. Section 6 documents the code for the `\mathfont` command itself. Section 7 contains the code for local font changes. Section 8 contains miscellaneous material. Sections 9–11 contain the Lua code to modify font objects at loading, and section 12 lists the unicode hex values used in symbol declaration. Version history and code index appear at the end of the document.

Acknowledgements: Thanks to Lyric Bingham for her work checking my unicode hex values. Thanks to Matthew Braham, Sergio Callegari, Daniel Flipo, Shyam Sundar, Adrian Vollmer, Herbert Voss, and Andreas Zidak for pointing out bugs in previous versions of **mathfont**. Thanks to Jean-François Burnol for pointing out an error in the documentation in reference to his **mathastext** package.

1 Setup

First, the package should declare itself. The first 61 lines of `mathfont.sty` are comments.

```
62 \NeedsTeXFormat{LaTeX2e}
63 \ProvidesPackage{mathfont}[2025/06/05 v. 2.4a]
```

Informational message.

```
64 \def\@mathfontinfo#1{\wlog{Package mathfont Info: #1}}
```

We specify conditionals and one count variable that we use later in handling options and setup.

```
65 \newif\ifM@XeTeXLuaTeX      % is engine one of xetex or luatex?
66 \newif\ifM@Noluaotfload    % cannot find luatofload.sty?
67 \newif\ifM@adjust@font     % should adjust fonts with lua script?
68 \newif\ifM@font@loaded      % load mathfont with font specified?
69 \newif\ifE@sterEggDecl@red % already did easter egg?
70 \newcount\M@loader         % specifies which font-loader to use
```

We disable the twenty user-level commands. If `mathfont` runs normally, it will overwrite these “bad” definitions later, but if it throws one of its two fatal errors, it will `\endinput` while the user-level commands are error messages. That way the commands don’t do anything in the user’s document, and the user gets information on why not. The bad definitions gobble their original arguments to avoid a “missing `\begin{document}`” error. To streamline the process, we metacode most of the error messages. We do so in three batches: those that `\@gobble` their argument, those that `\@gobbletwo` their argument, and those that accept an optional argument.

```
71 \long\def\@gobble@brackets[#1]{}
72 \def\M@NoMathfontError#1{\PackageError{mathfont}{%
73   \MessageBreak Invalid command\MessageBreak
74   \string#1 on line \the\inputlineno}%
75   {Your command was ignored. I couldn't\MessageBreak
76   load mathfont, so I never defined this\MessageBreak
77   control sequence.}}}
```

First the commands that normally accept a single argument—the “bad” versions `\@gobble` the argument. To keep the syntax straightforward, we put the `\def` declaration inside `\@tempa` and the definition itself inside `\@tempb`. We need to do this because the macro name is stored in `\@i`, and otherwise, we would end up with a mess of `\expandafters` to expand all instances of `\@i`.

```
78 \@tfor\@i:=\setfont
79   \RuleThicknessFactor
80   \IntegralItalicFactor
```

```

81  \SurdVerticalFactor
82  \SurdHorizontalFactor
83  \CharmLine
84  \CharmFile\do{%
85    \edef@\tempa{\protected\def\expandafter\noexpand\@i{%
86      \noexpand\MC@NoMathfontError\expandafter\noexpand\@i
87      \noexpand\@gobble}}}
88  \@tempa}

```

Now for the macros that `\@gobbletwo` their argument. The code is essentially the same.

```

89 \@tfor\@i:=\newmathrm
90   \newmathit
91   \newmathbf
92   \newmathbfit
93   \newmathsc
94   \newmathscit
95   \newmathbfsc
96   \newmathbfscit\do{%
97     \edef@\tempa{\protected\def\expandafter\noexpand\@i{%
98       \noexpand\MC@NoMathfontError\expandafter\noexpand\@i
99       \noexpand\@gobbletwo}}}
100  \@tempa}

```

For the optional argument, we check if the following character is a [. If yes, we gobble first the brackets and then the mandatory argument. If not, we gobble the single mandatory argument.

```

101 \protected\def\mathfont{%
102   \MC@NoMathfontError\mathfont
103   \@ifnextchar[{\expandafter\@gobble\@gobble@brackets}
104   {\@gobble}}
105 \protected\def\mathconstantsfont{%
106   \MC@NoMathfontError\mathconstantsfont
107   \@ifnextchar[{\expandafter\@gobble\@gobble@brackets}
108   {\@gobble}}

```

We code `\newmathfontcommand` by hand because it is the only command with four arguments.

```

\newmathfontcommand 109 \protected\def\newmathfontcommand{%
110   \MC@NoMathfontError\newmathfontcommand\@gobblefour}

```

Check that the engine is X_ET_EX or LuaT_EX. If yes, set `\ifM@XeTeXLuaTeX` to true. (Otherwise the conditional will be false by default.)

```

111 \ifdefined\directlua

```

```

112  \M@XeTeXLuaTeXtrue
113 \fi
114 \ifdefined\XeTeXrevision
115  \M@XeTeXLuaTeXtrue
116 \fi

```

The package can raise two fatal errors: one if the engine is not X_ET_EX or LuaT_EX (and cannot load OpenType fonts) and one if T_EX cannot find the luactfload package. In both cases, the package will stop loading, so we want a particularly conspicuous error message. For each message, we check the appropriate conditional to determine if we need to raise the error. If yes, we change space to catcode 12 inside a group. We define a **\GenericError** inside a macro and then call the macro for a cleaner error context line. The **\@gobbletwo** eats the extra period and return that L_AT_EX adds to the error message. Notice that we expand the error before the **\endgroup**—this is because we need to switch **\M@XeTeXLuaTeXError** with its replacement text while it is still defined before we leave the group. At the same time, we want **\AtBeginDocument** and **\endinput** outside the group. The second **\expandafter** means that we expand the final **\fi** before **\endinput**, which balances the original conditional.

```

117 \ifM@XeTeXLuaTeX\else
118 \begingroup
119 \catcode`\_ =12\relax
\M@XeTeXLuaTeXError 120 \def\M@XeTeXLuaTeXError{\GenericError{}%

133 {See the mathfont package documentation for explanation.}%
134 {I need XeTeX or LuaTeX to use mathfont. It\MessageBreak
135 looks like the current engine is something\MessageBreak
136 else, so I'm going to stop reading in the\MessageBreak
137 package file now. (You won't be able to use\MessageBreak
138 commands from mathfont in your document.) To\MessageBreak
139 load mathfont correctly, please retypeset your\MessageBreak

```

```

140 document with one of those two engines.^~J} }%
141 \expandafter\endgroup
142 \M@XeTeXLuaTeXError
143 \AtEndOfPackage{%
144   \typeout{:: mathfont :: Failed to load\online.}
145 \expandafter\endinput % we \endinput with a balanced conditional
146 \fi

```

Now do the same thing in checking for `luaotfload`. If the engine is LuaTeX, we tell `mathfont` to implement Lua-based font adjustments by default. The conditional `\ifM@Noluaotfload` will keep track of whether TeX could find `luaotfload.sty`. If the engine is XeTeX, issue a warning.

```

147 \ifdefined\directlua
148   \M@adjust@fonttrue % if engine is LuaTeX, adjust font by default
149   \IfFileExists{luaotfload.sty}
150     {\M@Noluaotfloadfalse\RequirePackage{luaotfload}}
151     {\M@Noluaotfloadtrue}
152 \else
153   \AtEndOfPackage{\PackageWarningNoLine{mathfont}{%
154     The current engine is XeTeX, but as\MessageBreak
155     of mathfont version 2.0, LuaTeX is\MessageBreak
156     recommended. Consider compiling with\MessageBreak
157     LuaLaTeX. Certain features will not\MessageBreak
158     work with XeTeX}}
159 \fi

```

If the engine is LuaTeX, we must have `luaotfload` because LuaTeX needs this package to load OpenType fonts. Before anything else, TeX should check whether it can find `luaotfload.sty` and stop reading in `mathfont` if it cannot. Same command structure as before. Newer L^AT_EX versions load `luaotfload` as part of the format, but it never hurts to double check.

```

160 \ifM@Noluaotfload % true if LuaTeX AND no luaotfload.sty
161 \begingroup
162 \catcode`\ =12\relax

282      to change a lightbulb??^~J^~J}
283      \EasterEggUpdate
284      \egroup}

```

One update at the first instance of math mode, assuming another package doesn't overwrite the contents of \everymath first.

```

285 \def\math@sterEggUpd@te{\begingroup
286   \let\ProcessE@sterEgg\relax
287   \def\E@sterEggUpd@te{Easter Egg Status:^^J^^J%
288     Scrambled, poached, or sunny side up?^^J^^J}%
289   \EasterEggUpdate
290   \endgroup
291   \global\let\math@sterEggUpd@te\relax}
292 \everymath\expandafter{\the\everymath\math@sterEggUpd@te}
```

Two status updates `\AtEndDocument`, including the egg itself. First, we disable `\ProcessE@sterEgg` since we don't need it anymore. Then inside a group, we make the control symbols `*`, `\/`, and `\=` expand to their own names and do some extreme catcode sports. We convert `+` to active and make it expand to a space. Because everything has already been tokenized inside `\DeclareOption`, we have to retokenize the definition of `+` inside `\scantokens`, and we set `\everyeof` to `\noexpand` to avoid an end-of-file error.

```

293 \AtEndDocument{\let\ProcessE@sterEgg\relax
294   \begingroup
295     \edef\*\{@backslashchar*}
296     \edef/\{@backslashchar/}
297     \edef\=@{@backslashchar=}
298     \catcode`\+=\active
299     \everyeof{\noexpand}
300     \scantokens{\def+{ }}}
```

At this point we are ready to make the egg message Again, we have to retokenize everything with `\scantokens` because it was previously tokenized. However, if we write `^^J` directly inside `\scantokens`, that primitive will convert the newline to a blank space, so instead we store `^^J` in `\@tempb`. After the `\edef` expands `\scantokens`, it also expands each `\@tempb`, so `\@tempa` has the line breaks we want.

```

301 \def\@tempb{^^J}
302 \edef\@tempa{\scantokens{Easter Egg Status:\@tempb\@tempb
303   The egg has been retrieved. What\@tempb
304   pinnacle of pulchritude!\@tempb\@tempb
305   +*****\@tempb
306   +*****\@tempb
307   +*****\@tempb
308   +-----\@tempb
309   +*****\@tempb
310   +***/\****/\****/\****/\****\@tempb
311   +***\****\****\****\****\****\@tempb
312   +*****\@tempb}
```

```

313      *****/*****/*****/****/*****/***\@tempb
314      ***\****/*****/****/*****/***\@tempb
315      ***\****/****\****\****\****\***\@tempb
316      *****/*****/*****\*****\*****\*****\@tempb
317      *****/*****/*****\****/*****\*****\@tempb
318      *****\****/****\****/*****\*****\@tempb
319      +****\****/****\****\****\*****\@tempb
320      +*****\*****\*****\*****\@tempb
321      +-----\@tempb
322      +*****\*****\*****\*****\@tempb
323      +*****\*****\*****\*****\@tempb
324      ++++++\=====/\@tempb
325      ++++++\=====/\@tempb

338      \EasterEggUpdate
339      \let\E@sterEggUpd@te\relax
340      \let\EasterEggUpdate\relax
341  \fi}%

```

The five real package options. The `default-loader` and `fontspec-loader` tell `mathfont` what to use as a backend for loading fonts.

```

342 \DeclareOption{default-loader}{\M@loader\z@}
343 \DeclareOption{fontspec-loader}{\M@loader\@ne}

```

The options `adjust` and `no-adjust` determine whether `mathfont` applies Lua-based font adjustments to fonts loaded in the future.

```

344 \DeclareOption{adjust}{\M@adjust@fonttrue}
345 \DeclareOption{no-adjust}{\M@adjust@fontfalse}

```

Interpret an unknown option as a font name and save it for loading. In this case, the package sets `\ifM@font@loaded` to true and stores the font name in `\M@font@load`.

```

346 \DeclareOption*{\M@font@loadedtrue
347   \edef\M@font@load{\CurrentOption}}
348 \ProcessOptions*
```

For the font-loader, we have a bit of processing to do. First print an informational message in the log file. The default loader is easy, but if the user requests `fontspec`, we have to make sure to load everything properly.

```

349 \ifcase\M@loader
350   \mathfontinfo{Default font-loader was

385     this error, make sure fontspec
386     is installed in \MessageBreak
387     a directory searchable by TeX or
388     load mathfont \MessageBreak
389     with the default-loader option. ^~J}
390     \M@loader \z@}
391 \fi

```

We print an informational message specifying the font-loader in use. We store default OpenType features in `\M@otf@features`. The contents depend on the font-loader because we use `XeTEX/luaotfload` syntax versus `fontspec` syntax. By default, `mathfont` loads fonts with Latin script, default language, `TEX` and common ligatures, and lining numbers.

```

392 \ifcase \M@loader

```

3 Default Settings

We save four macros from the L^AT_EX kernel for safe-keeping, and then we change their definitions. To make the symbol declaration macros from the kernel compatible with unicode fonts, we convert the hexadecimal digits in \count0 and \count2 back to decimal and change the \math primitive to \Umath.

```

630 \let\@@set@mathchar\set@mathchar
631 \let\@@set@mathsymbol\set@mathsymbol

Kernel command to set math characters from control sequences.

649 \def\set@mathsymbol#1#2#3#4{%
650   \multiply\count\z@ by 16\relax
651   \advance\count\z@\count\tw@
652   \global\Umathchardef#2=\mathchar@type#3+#1+\count\z@\relax}

Kernel command to set accents.

653 \def\set@mathaccent#1#2#3#4{%
654   \multiply\count\z@ by 16\relax
655   \advance\count\z@\count\tw@
656   \protected\xdef#2{%
657     \Umathaccent\mathchar@type#3+\number#1+\the\count\z@\relax}}

```

We increase the upper bound on the number of symbol fonts to be 256. \LaTeX and \XeTeX allow up to 256 math families, but the \LATEX kernel keeps the old upper bound of 16 symbol fonts under these two engines. We patch $\text{\DeclareSymbolFont}$ to change the \count18<15 to $\text{\count18 <\e@mathgroup@top}$, where \e@mathgroup@top is the number of math families, which is 256 in \XeTeX and \LaTeX . We get a sanitized definition with \meaning and \strip@prefix , implement the patch by expanding \M@p@tch@decl@re , and retokenize the whole thing. A simpler approach, such as calling \M@p@tch@decl@re directly on the expansion of $\text{\DeclareSymbolFont}$, won't work because of how \TeX stores and expands parameter symbols inside macros.

As of November 2022, the \LATEX team renamed $\text{\DeclareSymbolFont}$ to $\text{\DeclareSymbolFont@m@dropped}$, and now $\text{\DeclareSymbolFont}$ is a wrapper around the old version of itself. This was done for error checking purposes to remove extra $\text{m}'s$ from certain NFSS family names. This means that if $\text{\DeclareSymbolFont@m@dropped}$ is defined, we should patch that macro, and otherwise, we should patch $\text{\DeclareSymbolFont}$.

```

658 \ifx\DeclareSymbolFont@m@dropped\@undefined
659   \edef\@tempa{\expandafter
660     \strip@prefix\meaning\DeclareSymbolFont}
661   \def\@tempb{\def\DeclareSymbolFont##1##2##3##4##5}
662 \else
663   \edef\@tempa{\expandafter

```

```

664      \strip@prefix\meaning\DeclareSymbolFont@m@dropped}
665  \def@\tempb{\def\DeclareSymbolFont@m@dropped##1##2##3##4##5}
666 \fi
\M@p@tch@decl@re 667 \def\M@p@tch@decl@re#1<15#2\@nil{#1<\e@mathgroup@top#2}
\M@DecSymDef 668 \edef\@tempa{\expandafter\@tempb\expandafter\@nil}

```

Now `\M@DecSymDef` contains the patched text of our new `\DeclareSymbolFont`, all with catcode 12. In order to make it useable, we have to retokenize it. We use `\scantextokens` in `LuaTeX` and a safe version of `\scantokens` in `XETEX`. We store the `\def\DeclareSymbolFont` and parameter declaration in a separate macro `\@tempa` to make it easy to expand around them when we redefine `\DeclareSymbolFont`.

```

669 \ifdefined\directlua
670  \expandafter\@tempb\expandafter{\scantextokens
671    \expandafter{\M@DecSymDef}}

```

Unfortunately, while `\scantextokens` is straightforward, `\scantokens` is a menace. The problem is that when it expands, the primitive inserts an end-of-file token (because `\scantokens` mimics writing to a file and `\input`ing what it just wrote) after the retokenized code, and as a result, `\scantokens` can produce an end-of-file error. We can make the command usable by putting a `\noexpand` inside `\everyeof`. In order to prevent the `\edef` from also expanding our retokenized definition of `\DeclareSymbolFont`, we put the definition inside `\unexpanded`.

```

672 \else
673  \begingroup
674  \everyeof{\noexpand}

```

The first `\edef` expands `\M@DecSymDef` and defines `\M@retokenize` to be `\scantokens{\unexpanded{{new definition}}}`, and the second `\edef` carries out the retokenization. Once we have stored the patched definition in `\M@retokenize`, we expand `\M@retokenize` before the `\endgroup` and redefine `\DeclareSymbolFont` by calling `\@tempa`.

```

\@retokenize 675 \edef\@retokenize{\noexpand\scantokens
676   {\noexpand\unexpanded{\M@DecSymDef}}}
\@retokenize 677 \edef\@retokenize{\@retokenize}
678 \expandafter\endgroup
679 \expandafter\@tempb\expandafter{\@retokenize}
680 \fi

```

We need to keep track of the number of times we have loaded fonts, and `\M@count` fulfills this role. The `\toks` will record a message that displays in the `log` file when the user calls `\mathfont`. The `\newread` is for `Lua`-based font adjustments.

748 \def\M@frakshape{upright}            % fraktur
749 \def\M@bcalshape{upright}            % bold caligraphic
750 \def\M@bfrakshape{upright}           % bold fraktur

```

The `\M@keys` list stores all the possible keyword options, and `\M@defaultkeys` stores the character classes that `\mathfont` acts on by default.

```

\begin{array}{ll}
\text{\M@keys} & 751 \def\M@keys{upper,lower,diacritics,greekupper,%
752   greeklower,agreekupper,agreeklower,cyrillicupper,%
753   cyrilliclower,hebrew,digits,operator,delimiters,%
754   radical,bigops,extbigops,symbols,extsymbols,arrows,%
755   bb,cal,frak,bcal,bfrak} \\
\text{\M@defaultkeys} & 756 \def\M@defaultkeys{upper,lower,diacritics,greekupper,%
757   greeklower,digits,operator,symbols}
\end{array}

```

If the user enabled Lua-based font adjustments, the `\M@defaultkeys` list also includes delimiters, surd, and big operator symbols.

```
758 \ifM@adjust@font
\M@defaultkeys 759   \edef\M@defaultkeys{\M@defaultkeys,delimiters,radical,bigops}
760 \fi
```

4 Fontloader

We come to the fontloader. The main font-loading macro is `\M@newfont`. It expects a font name and OpenType feature information in its argument, and it parses the information, adds fonts to the NFSS if necessary, and stores NFSS font family names in `\M@f@ntn@me` and `\M@f@nt@n@me@base`. (Advanced users: please do not call `\M@newfont` directly because its implementation may change. Instead call `\mathfont` with the `empty` keyword and extract the NFSS family name from `\M@f@ntn@me` or `\M@f@ntn@meb@se`.) Our general approach is to feed the mandatory argument of `\mathfont` to `\M@newfont`, then proceed in one of three ways: (1) if the argument of `\mathfont` corresponds to a font family already in the NFSS, including one that `mathfont` created through the built-in font-loader, check what shapes are present and issue a warning if we appear to be missing any important ones; (2) if the argument is not a family in the NFSS and `\M@loader` is 0, we use the default font-loader, which is essentially a wrapper around code that we would expect to find in a typical `fd` file; or (3) otherwise, we feed the font name and feature information directly to `fontspec` and save the corresponding family name for reference later.

We use two control sequences for the family names because in `LuaTeX`, we load the font twice. The first time uses a default or user-specified renderer (typically node mode), and the second time uses base mode. Node mode is better for text, but it has more limited capabilities in math mode. Accordingly, we use a node-mode version of the font for text and the base-mode version for math, and advanced users who want to manually switch to a given `\fontfamily` at some point in their document are probably better off using the family that `mathfont` loaded with the default renderer. The package stores the NFSS family name for this version of the font in `\M@f@ntn@me`, and `\M@f@nt@n@me@base` contains the NFSS family name of the base-mode version. In `XeTeX`, these control sequences will be identical. Given a font family name from `\M@f@ntn@me`, it is possible to find the corresponding base-mode family name by calling `\csname \M@f@ntn@me-base\endcsname`. With `mathfont`'s built-in font-loader, the family name will be the mandatory argument of `\mathfont` with spaces removed, and the family name from using `fontspec` will be different.

We begin with commands to add series and shape information to the NFSS for a given font family. The `\M@declare@shape` macro takes several arguments. It checks whether the series/shape pair exists in the NFSS, and if not, it adds it using `\DeclareFontShape`. The argument structure is

- #1—NFSS font family name
- #2—optional /B or /I (or /BI) suffix on the font name
- #3—a list of (default) OpenType feature tags
- #4—a list of (the user's) OpenType feature tags
- #5—NFSS series identifier
- #6—NFSS shape identifier

We assume that the font file reference has already been stored in `\@tempbase`.

```
\M@declare@shape 761 \def\@tempbase{\M@declare@shape#1#2#3#4#5#6{%
762   \ifcsname TU/#1/#5/#6\endcsname
763   \else
764     \DeclareFontShape{TU}{#1}{#5}{#6}{<->"\@tempbase#2:#3:#4"}{}
765   \fi}
```

The `\M@fill@nfss@shapes` command does the work of populating the NFSS with the correct shape information. The argument structure is:

- #1—NFSS font family name
- #2—a list of (default) OpenType feature tags
- #3—a list of (the user's) OpenType feature tags

We call `\M@declare@shape` for each combination of medium/bold series and upright/italic shape, and the result is an entry in the NFSS for each combination. We have separate declarations for regular and small caps because they have different shape identifiers in the NFSS. We manually set `smcp` to be `true` or `false` accordingly.

```
\M@fill@nfss@shape 766 \def\@tempbase{\M@fill@nfss@shapes#1#2#3{%
767   \@for\@i:=#1{\{}{\#2;-smcp}{\#3}{\mddefault}{\shapedefault},%
768   {\#1}{/I}{\#2;-smcp}{\#3}{\mddefault}{\itdefault},%
769   {\#1}{/B}{\#2;-smcp}{\#3}{\bfdefault}{\shapedefault},%
770   {\#1}{/BI}{\#2;-smcp}{\#3}{\bfdefault}{\itdefault},%
```

And do small caps. If a small caps font face is separate from the main font file, TeX won't be able to find it automatically. In that case, you will have to write your own `fd` file or `\DeclareFontShape` commands.

```
771   {\#1}{\{}{\#2;+smcp}{\#3}{\mddefault}{\scdefault},%
772   {\#1}{/I}{\#2;+smcp}{\#3}{\mddefault}{\scdefault\itdefault},%
773   {\#1}{/B}{\#2;+smcp}{\#3}{\bfdefault}{\shapedefault},%
774   {\#1}{/BI}{\#2;+smcp}{\#3}{\bfdefault}{\scdefault\itdefault}%
775   \do{\expandafter\@tempbase\@i}}
```

The `\M@check@nfss@shapes` macro checks if a font family has shapes declared in upright, italic, bold, and bold italic. If any of those shapes are missing, we issue a warning. We store the missing series/shape pairs in `\@tempb` to print them as part of the warning message.

```
\M@check@nfss@shap 776 \def\M@check@nfss@shapes#1{%
 777   \let\@tempb\@empty
 778   \let\@tempwarning\@gobble
 779   \@for\@i:=\mddefault/\shapedefault,%
 780     \mddefault/\itdefault,%
 781     \bfdefault/\shapedefault,%
 782     \bfdefault/\itdefault\do{%
 783       \expandafter\ifx\csname TU/#1/\@i\endcsname\relax
 784         \def\@tempwarning{\M@MissingNFSSShapesWarning{#1}}
 785         \edef\@tempb{\@tempb, \@i}
 786       \fi}
```

We use a small hack to get everything to print correctly. If all shapes are present, then `\@tempwarning` is `\@gobble`, and the argument disappears. Otherwise, the argument becomes part of the warning message. The `\@gobble` eats the (unnecessary) first comma inside `\@tempb`.

```
787   \@tempwarning{\expandafter\@gobble\@tempb}}
```

We use `\M@split@colon` and `\M@strip@colon` for parsing the argument of `\mathfont`. If the user calls `\mathfont{<name>}{<features>}`, we store the name in `\@tempbase` and the features in `\@tempfeatures`. If the user specifies a name only, then `\@tempfeatures` will be empty. Syntactically, we use `\M@strip@colon` to remove a final : the same way we remove a final = when we parse the optional argument in the next section.

```
\M@split@colon 788 \def\M@split@colon#1:#2\@nil{%
  \@tempbase 789   \def\@tempbase{#1}
  \@tempfeatures 790   \def\@tempfeatures{#2}}
\@tempbase 791 \def\@tempbase{#1}
```

The main font-loading macro. The command takes a single argument, which should have the form `<NFSS family>` or `:{<optional features>}`, and it begins by parsing the argument. It splits the argument at a : and stores each portion in `\@tempbase` and `\@tempfeatures`. If `\@tempfeatures` is not empty, it has an extra colon at the end. We remove it. Previous versions of `mathfont` allowed users to say `\mathfont{fontspec}`, but this functionality is no longer supported.

```
\M@newfont 792 \def\M@newfont#1{%
 793   \edef\@tempa{#1}
 794   \expandafter\@tempb\@tempa:\@nil
```

```

795   \ifx\@tempfeatures\empty\else
\@tempfeatures 796     \edef\@tempfeatures{\expandafter\M@strip@colon\@tempfeatures}
797   \fi

```

First we check if the argument is an entry in the NFSS. If yes, we check if the shapes are present using `\M@check@nfss@shapes`. We assume that if the user specifies a font family identifier here, they know what they are doing, and the font-loader makes no attempt to fill in missing shapes.

```

798 \ifcsname TU+\@tempbase\endcsname % is font family in the nfss?
799   \let\M@f@ntn@me\@tempbase
800   \M@check@nfss@shapes\M@f@ntn@me
801   \ifx\directlua\undefined % if XeTeX
802     \expandafter\edef
803       \csname\M@f@ntn@me-base\endcsname{\M@f@ntn@me}
804   \let\M@f@ntn@meb@se\@f@ntn@me
805   \else % if LuaTeX

```

With `LuaTEX`, we would like to have a proper base-mode version of the font. If the font declaration happened outside of `mathfont` and the engine is `LuaTEX`, then `mathfont` expects to find another font family whose NFSS identifier is stored in `\langle font family\rangle-base`, and we assume this second font was loaded with `mode=base`. If that information exists, we use it for the base-mode version. Otherwise, we issue a warning if the engine is `LuaTEX`.

```

806   \ifcsname\@f@ntn@me-base\endcsname % if base-mode version
807     \edef\@f@ntn@meb@se
808       {\csname\@f@ntn@me-base\endcsname}
809       \M@check@nfss@shapes\@f@ntn@meb@se
810   \else
811     \M@NoBaseModeDetectedWarning{\@f@ntn@me}
812     \edef\@f@ntn@meb@se{\@f@ntn@me}
813     \expandafter\edef
814       \csname\@f@ntn@me-base\endcsname{\@f@ntn@me}
815   \fi
816 \fi

```

Now save the font families for reference later.

```

817   \expandafter\edef
818     \csname\@fontfamily@\@tempbase\endcsname
819     {\@f@ntn@me}
820   \expandafter\edef
821     \csname\@fontfamily@base@\@tempbase\endcsname
822     {\@f@ntn@meb@se}
823 \else

```

If the argument is not a font family identifier, then we check if `mathfont` has previously loaded a font using this argument. If yes, it will be stored in `\M@fontfamily@<arg>`, and we use the font family name from the previous call to `\M@newfont`. We remove the spaces before using the argument because in general, we do not want `mathfont` to use space characters internally to distinguish font names.

```

824      \edef@nospace{@tempa{\@tempa}
825      \ifcsname M@fontfamily@\@tempa\endcsname
826          \edef\M@f@ntn@me{\csname M@fontfamily@\@tempa\endcsname}
827          \edef\M@f@ntn@meb@se
828              {\csname M@fontfamily@base@\@tempa\endcsname}
829      \else

```

If `\M@newfont` doesn't find anything previously that matches #1, we load the font. Under the built-in font-loader, the name for the font family will be #1 with spaces removed, which we store in `\M@f@ntn@me`. (A properly declared NFSS font family does not have spaces in its name because L^AT_EX ignores spaces when scanning a font family declaration.) Then we call `\M@fill@nfss@shapes` to declare all the shapes.

```

830      \edef@nospace{@tempa{\@tempa}
831      \ifcase\@loader % are we using default font-loader?
832          \let\@mathfontinfo{^^JAdding \@tempbase\space
833              to the nfss!}
834          \wlog{Family name: \M@f@ntn@me}
835          \DeclareFontFamily{TU}{\M@f@ntn@me}{}%
836          \M@fill@nfss@shapes{\M@f@ntn@me}{\M@otf@features}
837              {\@tempfeatures}
838

```

If the engine is LuaT_EX, we load a separate version of the font with `mode=base`. Then we link the base-mode and regular versions.

```

839      \ifdefined\directlua
840          \edef\@M@f@ntn@meb@se{\M@f@ntn@me-base}
841              \@mathfontinfo{Adding \@tempbase\space with mode=base
842                  to the nfss!}
843          \wlog{Family name: \M@f@ntn@meb@se}
844          \DeclareFontFamily{TU}{\M@f@ntn@meb@se}{}%
845          \M@fill@nfss@shapes{\M@f@ntn@meb@se}{\M@otf@features}
846              {\@tempfeatures;mode=base}
847      \else
848          \edef\@M@f@ntn@meb@se{\M@f@ntn@me}
849      \fi
850      \or % are we using fontspec as font-loader?

```

If the user requested `fontspec` as the font-loader, we pass the font name and features to `\fontspec_set_family:Nnn` for loading and store the NFSS family name in `\M@f@ntn@me`. In `LuaTeX`, we request a separate base-mode version by specifying `Renderer=Base`.

```

851      \@mathfontinfo{^^JPassing \@tempbase\space
852          to fontspec for handling!}
853      \csname fontspec_set_family:Nnn\endcsname\M@f@ntn@me
854          {\M@otf@features,\@tempfeatures}{\@tempbase}
855      \ifdefined\directlua
856          \@mathfontinfo{Passing \@tempbase\space
857              with Renderer=Base to fontspec for handling!}
858          \csname fontspec_set_family:Nnn\endcsname\M@f@ntn@meb@se
859              {\M@otf@features,\@tempfeatures,Renderer=Base}
860              {\@tempbase}
861      \else
862          \edef\M@f@ntn@meb@se{\M@f@ntn@me}
863      \fi
864  \fi

```

Now link the base-mode family name and store the family names for future reference.

```

865      \expandafter\edef\csname\M@f@ntn@me-base\endcsname
866          {\M@f@ntn@meb@se}
867      \expandafter\edef\csname M@fontfamily@\@tempa\endcsname
868          {\M@f@ntn@me}
869      \expandafter\edef\csname M@fontfamily@base@\@tempa\endcsname
870          {\M@f@ntn@meb@se}
871  \fi
872 \fi}

```

Finally, the font-loading commands should appear only in the preamble.

```

873 \onlypreamble\M@declare@shape
874 \onlypreamble\M@fill@nfss@shapes
875 \onlypreamble\M@newfont

```

At this point, the font information is stored in the NFSS, but nothing has been loaded. For text fonts, that happens during a call to `\selectfont`, and for math fonts, that happens the first time entering math mode. I've considered forcing some fonts to load now, but I'm hesitant to change `LATEX`'s standard font-loading behavior. On this issue, I plan to leave `mathfont` as is for the foreseeable future. (Which probably means forever because backwards compatibility.)

5 Parse Input

This section provides the macros to parse the optional argument of `\mathfont`. We have two parts to this section: error checking and parsing. For parsing, we extract option and suboption information, and for error checking, we make sure that both are valid. The command `\M@check@option@valid` accepts a macro containing (what is hopefully) the text of a keyword-option. The macro defines `\@temperror` to be an invalid option error and loops through all possible options. If the argument matches one of the correct possibilities, `mathfont` changes `\@temperror` to `\relax`. The macro ends by calling `\@temperror` and issuing an error if and only if the argument is invalid. If `\M@check@option@valid` finds a valid keyword-option, it changes `\if@optionpresent` to true.

```
\M@check@option@va 876 \def\@check@option@valid#1{%
 877   \let\@temperror\@InvalidOptionError % error by default
 878   \@for\@j:=\M@keys\do{%
 879     \ifx\@j#1
 880       \let\@temperror\@gobble % eliminate error
 881       \optionpresenttrue      % set switch to true
 882     \fi}
 883   \def\@j{empty} % if option is "empty," we do nothing
 884   \ifx\@j#1
 885     \let\@temperror\@gobble
 886     \optionpresentfalse
 887   \fi
 888   \@temperror{#1}}
```

Do the same thing for the suboption.

```
\M@check@suboption 889 \def\@check@suboption@valid#1{%
 890   \let\@temperror\@InvalidSuboptionError % error by default
 891   \@for\@j:=roman,upright,italic\do{%
 892     \ifx\@j#1
 893       \let\@temperror\@gobble % eliminate error
 894       \suboptionpresenttrue % set switch to true
 895     \fi}
 896   \@temperror{#1}}
```

Now we have to actually parse the optional argument. We want to allow the user to specify options using an `xkeyval`-type syntax. However, we do not need the full package; a slim 30 lines of code will suffice. When `\mathfont` reads one segment of `text` from its optional argument, it calls `\M@parse@option<text>=\@nil`. The `\M@parse@option` macro splits the option and suboption by looking for the first `=`. It puts its `#1` argument (hopefully the keyword-option) in `\@temp@opt` and puts `#2` (hopefully the keyword-suboption) in `\@temp@sub`. If the user spec-

ifies a suboption, `\@tempb` contains $\langle suboption \rangle =$, and we use `\M@strip@equals` to get rid of the extra `=`. If the user does not specify a suboption, `\@tempb` will be empty.

```

\@strip@equals 897 \def\@strip@equals#1={#1}
\@parse@option 898 \def\@parse@option#1=#2@nil{%
  899   \@optionpresentfalse % set switch to false by default
  900   \@suboptionpresentfalse % set switch to false by default
  901   \def\@temp@opt{#1} % store option
  902   \def\@temp@sub{#2} % store suboption

```

After storing the option in `\@temp@opt` and suboption in `\@temp@sub`, check for errors. We check for errors by determining if (1) `\@tempa` is empty, meaning the user did not specify an option; or (2) `\@tempb` is `=`, meaning the user typed `=` but did not follow it with a suboption.

```

903   \ifx\@temp@opt\@empty
904     \M@MissingOptionError
905   \else

```

Check that the user specified a valid option. We redefine `\@tempa` inside a group to keep the change local, and we end the group as quickly as possible after the comparison, which means separate `\egroups` in both branches of `\ifx`.

```

906   \M@check@option@valid\@temp@opt
907   \bgroup\def\@tempa{=}
908   \ifx\@temp@sub\@tempa
909     \egroup % first branch \egroup
910     \M@MissingSuboptionError
911   \else
912     \egroup % second branch \egroup

```

If `\@temp@sub` is nonempty, strip the final `=` and check that it contains a valid suboption.

```

913   \ifx\@temp@sub\@empty
914   \else
915     \edef\@temp@sub{\expandafter\@strip@equals\@temp@sub}
916     \M@check@suboption@valid\@temp@sub % is suboption legit?
917   \fi
918 \fi

```

If the user specified suboption `roman`, we accept it for backwards compatibility and convert it to `upright`. Again, we redefine `\@tempa` inside a group to keep the change local.

```

919   \bgroup\def\@tempa{roman}
920   \ifx\@temp@sub\@tempa
921     \egroup % first branch \egroup

```

```

922      \def\@temp@sub{upright}
923      \else
924      \egroup % second branch \egroup
925      \fi
926 \fi}

```

We code a general-purpose definition macro that defines its first argument to be the second argument fully expanded and with spaces removed.

```

927 \long\def\edef@nospace#1#2{%
928   \edef#1{#2}%
929   \edef#1{\expandafter\zap@space#1 \empty}}

```

Perhaps something that sets spaces to `\catcode9` and then retokenizes #2 would be better, but I don't think it matters very much.

6 Default Font Changes

This section documents default math font changes. The user-level font-changing command is `\mathfont`, and it feeds the font information to `\@mathfont`, the internal command that does the actual font changing. This macro is basically a wrapper around `\DeclareSymbolFont` and a bunch of calls to `\DeclareMathSymbol`, and when the user calls `\@mathfont`, the command declares the user's font in the NFSS with `\M@newfont` and loops through the optional argument. On each iteration, `\@mathfont` validates the option and suboption, calls `\DeclareSymbolFont` if necessary, and sets the math codes with `\M@<keyword>@set`.

```
930 \protected\def\mathfont{\@testopt{\@mathfont}{\M@defaultkeys}}
```

The internal font-changing command. As of version 2.4, I'm taking out `\restoremathinternals`, so we don't need to check for restored primitives anymore.

```

931 \def\@mathfont[#1]#2{%
932   \M@toks{}}

```

We call `\M@newfont` on the mandatory argument of `\mathfont`, which stores the two NFSS family names (one for default renderer and one for base-mode renderer if using LuaTeX) in `\M@f@ntn@me` and `\M@f@ntn@mb@se`. If we need a new value of `\M@count`, we store it in `\M@fontid@<NFSS family name>`. We will not need a new value of `\M@count` if the user asks for the same NFSS font family twice. Throughout the definition of `\mathfont`, `\@tempa` stores the value of `\M@count` that corresponds to the current font.

```

933 \M@newfont{#2}
934 \ifcsname M@fontid@\M@f@ntn@me\endcsname % need new \M@count?

```

```

935   \else
936     \expandafter\edef
937       \csname M@fontid@M@f@ntn@me\endcsname{\the\M@count}
938     \expandafter\edef
939       \csname M@fontid@M@f@ntn@m@eb@se\endcsname{\the\M@count}
940     \advance\M@count\@ne
941   \fi
942 \edef\@tempa{\csname M@fontid@M@f@ntn@me\endcsname}

```

Expand, zap spaces from, and store the optional argument in `\@tempa`, and then perform the loop. We store the current keyword-suboption pair in `\@i` and then feed it to `\M@parse@option`. We need two `\edefs` here because `\zap@space` appears before `\@tempa` in `\M@eat@spaces`. We expand the argument with the first `\edef` and remove the spaces with the second.

```

943 \edef\nospace{@tempb{\#1}}
944 \@for\@i:=\@tempb\do{\expandafter\M@parse@option\@i=\@nil
945   \if@optionpresent

```

If the user calls `\mathfont` and tries multiple times to set the font for a certain class of characters, `mathfont` will issue a warning, and the package will not adjust the font for those characters. Notice the particularly awkward syntax with the `\csname-\endcsname` pairs. Without this construct, TeX won't realize that `\csname if@\@tempa\endcsname` matches the eventual `\fi`, and the `\@for` loop will break. (TeX does not have a smart if-parser!)

```

946   \expandafter\ifx % next lines are two cs to be compared
947     \csname ifM@\@tempo@opt\expandafter\endcsname
948     \csname iftrue\endcsname
949     \M@CharsSetWarning{@tempo@opt}
950   \else

```

The case where the current option has not had its math font set. We add the keyword-option to the `\toks`.

```

951   \edef\@tempc{\the\@toks^{\@tempo@opt}}
952   \M@toks\expandafter{\@tempc}

```

If it's present, store the suboption in `\@<option>shape` and overwrite the default definition from earlier. Then add the shape information to the toks and store it in `\@tempc`. When it actually sets the font by calling `\M@<keyword>@set`, `mathfont` will determine shape information for the current character class by calling the same `\@<option>shape` macro that we store in `\@tempc`.

```

953   \if@suboptionpresent
954     \expandafter\edef
955       \csname M@\@tempo@opt shape\endcsname{\@tempo@sub}
956   \fi

```

```

957      \edef\@tempc{\the\M@toks\space
958          (\csname M@\@tempc\shape\endcsname)}
959      \M@toks\expandafter{\@tempc}
960      \edef\@tempc{\csname M@\@tempc\shape\endcsname}

```

We store the font shape information in `\@tempb`, specifically `\@tempb` will be the default NFSS shape code corresponding to the current suboption. At this point, `\@tempc` is either “upright” or “italic,” so we temporarily let `\@tempb` be the string “upright” and check if it equals `\@tempc`. We redefine `\@tempb` depending on the results.

```

961      \def\@tempb{upright}
962      \ifx\@tempb\@tempc
963          \let\@tempb\shapedefault
964      \else
965          \let\@tempb\itdefault
966      \fi

```

At this point we have the information we need to declare the symbol font, namely the NFSS family (`\M@f@ntn@me`), series (`\mddefault`), and shape (`\@tempb`). The symbol font name will be $M(<\text{suboption}>)(\text{value of } M@count)$. We check if the symbol font we need for the current set of characters is defined, and if not, we define it using this information.

```

967      \ifcsname symM@\@tempc\@tempa\endcsname\else
968          \M@SymbolFontInfo{\@tempbase}{\M@f@ntn@me@se}
969              {\mddefault/\@tempb}{M@\@tempc\@tempa}
970          \DeclareSymbolFont{M@\@tempc\@tempa}{TU}
971              {\M@f@ntn@me@se}{\mddefault}{\@tempb}
972      \fi

```

We store the new font information so we can write it to the `log` file `\AtBeginDocument` and send an informational message to the user.

```

973      \expandafter\edef
974          \csname M@\@tempc\fontinfo\endcsname{\@tempbase}
975          \M@FontChangeInfo{\@tempc\@tempbase}

```

We have extra information to keep track of when `\@tempc` is `bb`, `cal`, `frak`, `bcal`, or `bfrak` because then `mathfont` effectively creates a new local font-change command, and we want to make sure that information gets added to `\M@localfonts`.

```

976      \otfor\@j:={bb}{cal}{frak}{bcal}{bfrak}\do{%
977          \ifx\@tempc\@j
978              \expandafter\@addto\localfonts
979                  {\expandafter\string
980                      \csname math\@tempc\endcsname}

```

```

981          {\@tempbase}
982          \@break@tfor
983          \fi}

```

And now the magic happens!

```

984      \csname M@\@temp@opt @set\endcsname % set default font
985      \csname M@\@temp@opt true\endcsname % set switch to true
986      \fi
987      \fi}

```

Display concluding messages for the user.

```

988 \edef\@tempa{\the\MToks}

  1007 \onlypreamble\setfont

```

The macro `\mathconstantsfont` chooses a font for setting math parameters. It is intended for LuaTeX when `mathfont` can adjust text fonts and add a MathConstants table. It issues a warning if called without font adjustments enabled. First, it checks if the argument was previously fed to `\mathfont` by seeing whether `\M@fontfamily@(#1)` is equal to `\relax`. If yes, #1 was never an argument of `\mathfont`, and we raise an error.

```

\m@th@const@nts@fo 1034 \let\m@th@const@nts@font\@tempa

```

We come to the tricky problem of making sure to use the correct MathConstants table. \LaTeX automatically initializes all math parameters based on the most recent \textfont, etc. assignment, so we want to tell \LaTeX to re-assign whatever default font we're using to the correct math family whenever we load new math fonts. This is possible, but the implementation is super hacky. When \LaTeX enters math mode, it checks whether it needs to redo any math family assignments, typically because of a change in font size, and if so, it calls \getanddefine@fonts repeatedly to append \textfont, etc. assignments onto the macro \math@fonts. Usually \math@fonts is empty because this process always happens inside a group, so we can hook into the code by defining \math@font to be \aftergroup<extra code>. In this case, the *extra code* will be another call to \getanddefine@fonts.

We initialize \M@SetMathConstants to be \relax, and we define it the first time the user calls \mathconstantsfont. When that happens, mathfont

begins by calling `\getanddefine@fonts` inside a group and uses as arguments the upright face of the font corresponding to #1. That puts the `\textfont`, `\scriptfont`, and `\scriptscriptfont` assignments corresponding to #1 inside `\math@fonts`. Then we call `\math@fonts`, and to avoid an infinite loop, we gobble the `\aftergroup\MCSetMathConstants` macros that `mathfont` has inserted at the start of `\math@fonts`. Setting `\globaldefs` to 1 makes the `\textfont`, etc. assignments from `\getanddefine@fonts` global when we call `\math@fonts`.

```

\MCSetMathConstant 1035 \protected\def\MCSetMathConstants{%
1036   \begingroup
1037   \escapechar\m@ne
1038   \expandafter\getanddefine@fonts

1053 \fi}
\math@fonts 1054 \def\math@fonts{\aftergroup\MCSetMathConstants}
1055 @onlypreamble\mathconstantsfont

```

If the user did not enable Lua font adjustments, then `\mathconstantsfont` will generate an error message and gobble its argument. This definition happens later in `mathfont.sty` when we define other Lua-related macros such as `\IntegralItalicFactor` to do the same thing absent font adjustments.

7 Local Font Changes

This section deals with local font changes. The `\newmathfont` command creates macros that change the font for math alphabet characters and is basically a wrapper around `\DeclareMathAlphabet`. First we code `\MCcheck@csarg`, which accepts two arguments. The #1 argument is the user-level command that

called `\M@check@csarg`, which we use for error messaging, and #2 should be a single control sequence. The way `\M@check@csarg` scans the following tokens is a bit tricky: (1) check the length of the argument by seeing if `\@gobble` eats it completely; and (2) check that the argument is a control sequence. If the user specifies an argument of the form `{..}`, i.e. extra text inside braces, the `\ifcat` will catch it and issue an error. If `\M@check@csarg` likes the input, it sets `\ifM@good@arg` to true, and otherwise, it sets `\ifM@arg@good` to false.

```
\M@check@csarg 1056 \def\M@check@csarg#1#2{%
 1057   \expandafter\ifx\expandafter\@nnil\@gobble#2\@nnil % good
 1058   \ifcat\relax\noexpand#2 % good
 1059     \M@arg@goodtrue
 1060   \else % if #2 not a control sequence
 1061     \M@MissingControlSequenceError#1{#2}
 1062     \M@arg@goodfalse
 1063   \fi
 1064 \else % if #2 is multiple tokens
 1065   \M@DoubleArgError#1{#2}
 1066   \M@arg@goodfalse
 1067 \fi}
```

The macro `\M@checkspecials` accepts a control sequence as its #1 argument and a font name as its #2 argument, and it checks whether #1 is `\mathbb` or a related command. If yes, we assume that the user is using some variant of `\newmathrm` instead of `\mathfont[bb]`, so we do some processing analogous to what we do inside `\mathfont`.

```
\M@checkspecials 1068 \def\M@checkspecials#1#2{%
 1069   \in@#1{\mathbb\mathcal\mathfrak\mathbfcal\mathbffrak}
 1070   \ifin@
```

We set `\escapechar` to -1 and use `\@gobblefour` to remove the `\math` from the start of #1. The string of `\expandafters` hits the `\string` inside `\@tempa`, and then the `\edef` expands the `\@gobblefour`. We are left with just the keyword inside `\@tempa`.

```
1071   \begingroup
1072     \escapechar\m@ne
1073     \expandafter
1074   \endgroup
1075   \expandafter\edef\expandafter\@tempa\expandafter{%
1076     \expandafter\@gobblefour\string#1}
```

Then write a message to the log file and set the corresponding boolean to true.

```
1077   \mathfontinfo{Interpreting your new macro \string#1\space
1078     as \@tempa\space chars.}
```

```

1079      \@mathfontinfo{Setting \expandafter\string
1080          \csname ifM@\@tempa\endcsname\space to true.}
1081      \csname M@\@tempa true\endcsname

```

And store the information to write to the log file `\AtBeginDocument`. The structure of `\M@<keyword>shape` is unusual because we want the macro to gobble “`\space shape`” in `\M@keyword@info@begin`.

```

1082      \expandafter\edef\csname M@\@tempa @fontinfo\endcsname{#2}
1083      \expandafter\edef\csname M@\@tempa shape\endcsname
1084          \space shape{inferred from \string#1}
1085  \fi}

```

Now declare the math alphabet. This macro first checks that its #1 argument is a control sequence using `\M@check@csarg`. If yes, load the #2 argument with `\M@newfont`, call `\DeclareMathAlphabet`, and check whether #1 is `\mathbb` or a related command, and finally add #1 and #2 to the list of local font-change commands.

```

\newmathfontcommand 1086 \protected\def\newmathfontcommand#1#2#3#4{%
1087   \M@check@csarg\newmathfontcommand{#1}
1088   \ifM@arg@good
1089     \M@newfont{#2}
1090     \M@NewFontCommandInfo{#1}{\@tempbase}{\M@f@ntn@meb@se}{#3}{#4}
1091     \DeclareMathAlphabet{#1}{TU}{\M@f@ntn@meb@se}{#3}{#4}
1092     \M@checkspecials{#1}{\@tempbase}
1093     \M@addto@localfonts{\string#1}{\@tempbase}
1094  \fi}
1095 \onlypreamble\newmathfontcommand

```

A helper macro that accepts two arguments. Its #1 argument is a control sequence (from `\string`), and the #2 argument is a font name. This macro checks whether #2 is a new font, increments `\M@num@localfonts` if so, and then adds both #1 and #2 to `\M@localfonts`. If `\M@localfonts` is `\@empty`, that means we haven’t added any fonts to the list yet, so in that case, we obviously increase `\M@num@localfonts`. Otherwise we loop through `\M@localfonts`, and if any of them are equal to `\@tempbase`, we do not need to increase `\M@num@localfonts`. We have to use `\@tempb` instead of `\@tempa` here because we use `\M@addto@localfonts` inside `\mathfont` where we need to preserve the definition of `\@tempb`.

```

\M@addto@localfont 1096 \def\M@addto@localfonts#1#2{%
1097   \ifx\M@localfonts\@empty
1098     \advance\M@num@localfonts\@ne
\@localfonts 1099     \edef\@localfonts{\#1\#2}
1100   \else

```

```

1101      \@tempswatrue      % increase by default
1102      \@for\@j:=\M@localfonts\do{%
1103          \edef\@tempb{\expandafter\@secondoftwo\@j}
1104          \ifx\@tempbase\@tempb
1105              \@tempswafalse % if \@tempbase is in list, don't add
1106          \fi}
1107      \if@tempswa
1108          \advance\M@num@localfonts\@ne
1109      \fi
1110      \edef\@localfonts{\@localfonts,{#1}{#2}}
1111  \fi}

```

Then define macros that create local font-changing commands with default series and shape information. Because they're all similar, we metacode them. We define the commands themselves with `\define@newmath@cmd`. The argument structure is:

- #1—`\newmath<key>` macro name
- #2—font series
- #3—font shape
- ##1—the user's control sequence
- ##2—the user's font information (family name)

We feed ##1, ##2, #2, and #3 to `\newmathfontcommand`, and we load ##2 with `\M@newfont`. Each `\newmath<key>` macro will check its first argument using `\M@check@csarg` and then call `\newmathfontcommand` on both of its two arguments. We store the list of `\newmath<key>` commands that we want to define with their series and shape information in `\M@default@newmath@cmds`, and we loop through it with `\@for`.

```

\@define@newmath@ 1112 \def\@define@newmath@cmd#1#2#3{%
1113     \protected\def#1##1##2{%
\@check@csarg 1114         \M@check@csarg{#1}{##1}
1115         \newmathfontcommand{##1}{##2}{#2}{#3}}}
\@default@newmath 1116 \def\@default@newmath@cmds{%
1117     \newmathrm{\mddefault}{\shapedefault},%
1118     \newmathit{\mddefault}{\itdefault},%

  1143  \newmathscit\mathscit{#1}
  1144  \newmathbfsc\mathbfsc{#1}
  1145  \newmathbfscit\mathbfscit{#1}}
  1146 @onlypreamble\setmathfontcommands

```

8 Miscellaneous

We begin this section with the user-level macros that provide information for Lua-based font adjustments. If font adjustments are allowed, we begin with a macro `\M@check@int` that checks whether #1 is a nonnegative integer. Depending on the result, `mathfont` sets `\ifM@arg@good` to true or false. The use of `\afterassignment` is inspired by `\@defaultunits` from the L^AT_EX kernel.

```

1147 \ifM@adjust@font
\newmath@check@int 1148  \def\newmath@check@int#1{%
  1149  \def\@tempa##1\relax{\def\@tempb{##1}}
  1150  \afterassignment\@tempa\count@=0#1\relax
  1151  \expandafter\ifx\expandafter\@nnnil\@tempb\@nnnil
  1152    \M@arg@goodtrue
  1153  \else
  1154    \M@arg@goodfalse
  1155  \fi}

```

We meta-code the definitions of `\RuleThicknessFactor`, etc. To keep the syntax relatively clean, we temporarily eliminate the `\escapechar` and redefine `\~` to `\noexpand`.

```

1156 \let\@tempa~
1157 \let~\noexpand
1158 \count@\escapechar
1159 \escapechar\m@ne
1160 \atfor@i:=\RuleThicknessFactor\IntegralItalicFactor
1161   \SurdHorizontalFactor\SurdVerticalFactor\do{%
1162     \protected\expandafter\edef\@i#1{%
1163       ~\M@check@int{\#1}%
1164       ~\ifM@arg@good
1165         ~\global\expandafter
1166           ~\csname
1167             M@\expandafter\string\@i
1168           \endcsname=\#1\relax
1169         ~\else
1170           ~\M@BadIntegerError\expandafter~\@i{\#1}%
1171         ~\fi}%
1172 \let~\@tempa
1173 \escapechar\count@

```

If automatic font adjustments are disabled, we should also disable the related user-level commands. In this case, each of the font-adjustment macros expands to raise an `\M@NoFontAdjustError` and gobble its argument.

```

1174 \else
1175   \atfor@i:=\RuleThicknessFactor\IntegralItalicFactor
1176     \SurdHorizontalFactor\SurdVerticalFactor\CharmLine\CharmFile
1177     \do{%
1178       \protected\expandafter\edef\@i{%
1179         ~\noexpand\M@NoFontAdjustError\expandafter\noexpand\@i
1180         ~\noexpand\@gobble}%
1181 \fi

```

These commands should appear in the preamble only.

```

1182 \@onlypreamble\RuleThicknessFactor
1183 \@onlypreamble\IntegralItalicFactor
1184 \@onlypreamble\SurdHorizontalFactor
1185 \@onlypreamble\SurdVerticalFactor
1186 \@onlypreamble\CharmLine
1187 \@onlypreamble\CharmFile

```

As of version 2.4, I'm taking out `\restoremathinternals`. We use the next three macros in defining `\simeq` and `\cong`. The construction is clunky and

needs the intermediate macro `\st@ck@fl@trel` because `\mathchoice` is a bit of an odd macro. It feels like it should be expandable, but it isn't. Instead, it fully typesets each of its four arguments and then takes the one corresponding to the correct style. A cleaner implementation would use `\mathstyle` from LuaTeX, but this control sequence isn't always accurate. In fact, the LuaTeX manual suggests that it is impossible to have an expandable version of `\mathchoice` that is always correct because of how TeX's math mode algorithm works..

```

```

Some fonts do not contain characters that `mathfont` can declare as math symbols. We want to make sure that if this happens, TeX prints a message in the `log` file and terminal.

```

1205 \ifnum\tracinglostchars<\tw@
1206   \tracinglostchars\tw@
1207 \fi

```

If `mathfont` is adjusting fonts, it also changes the `\Umathcodes` for Latin letters. As a result, math alphabet commands will no longer work for fonts where `mathfont` has not added new Latin letters in the correct encoding slots. The `\M@normal@mathcodes` macro addresses this issue by resetting all Latin letters to their usual encoding slots in math mode. This macro should always appear inside a group, and I am intending for it to be used alongside math alphabet commands from other packages. In particular, we use this macro to make `mathfont` compatible with any `\mathbb` or related commands that don't come from `mathfont`.

```

```

We loop through each `bb`, etc. keyword and check whether the corresponding `\math<keyword>` is defined. For convenience, we store `\math<keyword>` inside `\@tempa`. If the definition didn't come from `mathfont`, we wrap a call to `\M@normal@mathcodes` around the macro. This has to happen `\AtBeginDocument` because the user could load a package after `mathfont` that defines `\mathbb`.

```

1266  \AtBeginDocument{\@tfor\@i:={bb}{cal}{frak}{bcal}{bfrak}\do{%
1267    \ifcsname math\@i\endcsname

```

If `\math<keyword>` is defined, check whether the definition came from `mathfont`. Once again, we use `\ifx` with two booleans inside `\csname/\endcsname` pairs because otherwise TeX will get confused and think we have an unbalanced boolean inside `\@tfor`.

```

1268    \expandafter\ifx % next two lines are cs to be compared
1269      \csname ifM@\@i\expandafter\endcsname
1270      \csname ifffalse\endcsname % is \ifM@<keyword> false?

```

If `mathfont` did not define the control sequence, we have to do things. First an informational message in the log file.

```

1271  \mathfontinfo{Restoring \string\Umathcode\space values
1272    for \expandafter\string\csname math\@i\endcsname.}

```

Then save `\math<keyword>` as `\@@math<keyword>`, and make `\math<keyword>` into a wrapper around its original definition.

```

1273    \expandafter\let\csname @@math\@i\expandafter\endcsname
1274      \csname math\@i\endcsname
1275      \protected\expandafter\edef\csname math\@i\endcsname#1{%

```

```

1276      \begingroup
1277          \noexpand\mathcode`@normal@mathcodes
1278          \expandafter\noexpand\csname @@math\@i\endcsname{#1}
1279      \endgroup
1280      \fi
1281  \fi}

```

If `mathfont` is not adjusting fonts, then we do not need to change any `\Umathcodes`.

```

1282 \else
\mathcode`@normal@mathcode 1283 \let\mathcode`@normal@mathcodes\relax
1284 \fi

```

Now a messages about local font changes. We `\typeout` a message about local font-change commands.

```

1285 \AtBeginDocument{%
1286     \ifcase\localfonts
1287     \or
1288         \def\tempa#1#2#3\@nil{#2}
1289         \wlog{%
1290             \typeout{:: mathfont :: Using
1291                 \expandafter\tempa\mathcode`@localfonts\@nil\space
1292                 for local font changes.}
1293     \else
1294         \wlog{%
1295             \typeout{:: mathfont :: Using \the\localfonts\space
1296                 fonts for local font changes.}
1297     \fi}

```

Write to the `log` file `\AtBeginDocument` all font changes carried out by `mathfont`. The command `\@keyword@info@begin` accepts two arguments and prints an informational message about default font changes for keyword options for `\mathfont`. The `#1` argument is a keyword, and the `#2` argument is a number of spaces. The spaces make the messages line up with each other in the log file.

```

\@keyword@info@be 1298 \def\@keyword@info@begin#1:#2\@nil{%
1299     \expandafter\ifx % next lines are two cs to be compared
1300         \csname if#1\expandafter\endcsname
1301         \csname iftrue\endcsname
1302     \wlog{#1#2\@spaces\space\space\space Set to
1303         \csname M@#1@fontinfo\endcsname,
1304         \csname M@#1shape\endcsname\space shape}
1305 \else
1306     \wlog{#1#2\@spaces\space\space\space No change}

```

```
1307 \fi}
```

The macro `\M@local@info@begin` does the same thing except for the local font-change commands. The #1 argument is a control sequence from `\string`, and the #2 argument is a font name. We use `\count@` and `\@tfor` to count out the number of characters in #1, and if we get to 13, we cut it off and add three dots. We need to use this approach here because the control sequences in `\M@localfonts` have an unknown number of characters. We could have coded up an algorithm like this for `\M@keyword@info@begin` too, but I didn't do it before, and it won't make any practical difference to do it now.

```
\M@local@info@begi 1308 \def\M@local@info@begin#1#2{%
1309   \let\@tempa\@empty
1310   \count@0z0
1311   \@tfor\@i:=#1\do{%
1312     \edef\@tempa{\@tempa\@i}
1313     \advance\count@\@ne
1314     \ifnum\count@=15\relax
1315       \edef\@tempa{\@tempa...}
1316       \advance\count@\thr@@
1317       \@break@tfor
1318   \fi}
```

Now add spaces to `\@tempa` until we get up to 20 characters. At that point, we can write the message to the `log` file.

```
1319   \@whilenum\count@<20\do{%
1320     \edef\@tempa{\@tempa\space}
1321     \advance\count@\@ne}
1322   \wlog{\@tempa#2}
```

Now print the messages.

```
1323 \AtBeginDocument{%

9 Adjust Fonts: Setup

The next three sections implement Lua-based font adjustments and apply only if the user has enabled font adjustment. Most of the implementation happens through Lua code, but we need some TeX code in case the user wants to adjust character metric information. Here is a rough outline of what happens in the

next three sections:

1. Initialize a Lua table that contains new metrics for certain characters specific to math mode, such as letters with wider bounding boxes and large operator symbols.
2. Provide an interface for the user to change this metric information.
3. Write functions that accept a fontdata object and (a) change top-level math specs to indicate that we have a math function; (b) alter characters according to our Lua table of new metric information; and (c) populate a MathConstants table for the font.
4. Create callbacks that call these functions. Put a wrapper around them, and insert the wrapper-function into `luaotfload.patch_font`.

Step 2 happens on the \TeX side of things and is documented next, and everything else happens inside `\directlua`. On the Lua side of things, we store all the functions and character metric information in the table `mathfont`. Every entry in `mathfont` is a function or is a subtable indexed within `mathfont` by an *<integer>*. The *integer* is a unicode encoding number and tells which unicode character the subtable keeps track of. See tables 2 and 3 for a list of the functions in `mathfont` and the fields in character subtables. See section 11 for discussion of the callbacks for editing fontdata objects.

Changing top-level flags in a font object is straightforward. Creating a `MathConstants` table is complicated but largely self-contained. We take a few parameters that the user has set, define traditional \TeX math parameters based on the essential parameters of the font, and assign their values to corresponding entries in a `MathConstants` table. However, editing character metrics is convoluted with many moving parts. For every glyph that we want modify when \TeX loads a text font, we store character metric information about that glyph as a subtable in `mathfont`. The entries of the subtable describe how to stretch the glyph bounds, scale the glyph itself, or determine math accent placement. For characters of type `u`, we only specify accent placement. For characters of type `a`, which is the upper and lower-case Latin letters, we stretch the bounding box of the glyph horizontally to widen the letters slightly. When we load a text font, we create 52 virtual characters in the Unicode Supplementary Private Use Area-A that typeset the Latin letter glyphs in elongated bounding boxes, and later in `mathfont`, we set the `mathcodes` of Latin letters to be these virtual characters. For type `e`, we do the same thing except that for each character, we create an ensemble of scaled versions, which we use as a family of large variants.

Here's how to think about the dynamics of our approach. We use character metric information at three different times: pre-processing, interim processing,

Table 2: Fields of Character Subtables in `mathfont`

Field	Data Type	In a	In e	In u	Used For
<code>type</code>	string	Yes	Yes	Yes	Type is a, e, u
<code>next</code>	depends	Yes	Yes	No	Unicode index of next-larger character(s); integer for type a, table for type u
<code>left_stretch</code>	numeric	Yes	No	No	Stretch bounding box left
<code>right_stretch</code>	numeric	Yes	No	No	Stretch bounding box right
<code>top_accent_stretch</code>	numeric	Yes	Yes	Yes	Position top accent
<code>bot_accent_stretch</code>	numeric	Yes	Yes	Yes	Position bottom accent
<code>total_variants</code>	integer	No	Yes	No	Number of large variants
<code>smash</code>	integer	No	Yes	No	Unicode index for storing a smashed version
<code>data</code>	table	No	Yes	No	Scale factors

and post-processing. In pre-processing, which we implement in this section, we assemble initial character metric information into entries in `mathfont`. In other words, pre-processing means creating the initial `mathfont` subtables and happens during package loading. Interim processing means the user altering entries in `mathfont` and happens through `\CharmLine` and `\CharmFile`. This can occur at any point in the preamble. In post-processing, which we implement in the next section, `mathfont` extracts information from the current state of the `mathfont` table and uses it to alter a fontdata object. Post-processing happens through the `luaotfload.patch_font` callback and occurs once at the point when `TEX` loads the font file. As a rule, `LATEX` does not like to load fonts before it uses them, so post-processing typically happens `\AtBeginDocument` in the case of the main text font or whenever the user calls a `\text{font keyword}` command or enters math mode, whichever happens first. This is also why you cannot adjust fonts that `TEX` loaded before `mathfont`.

We set `mathnolimitsmode` to 4 to make integral signs look nice. Or at

Table 3: Functions in `mathfont`

Function	Argument(s)	Used For
<code>new_type_a</code>	<code>index, next, data</code>	Add type a entry to <code>mathfont</code>
<code>new_type_e</code>	<code>index, smash, next, data</code>	Add type e entry to <code>mathfont</code>
<code>new_type_u</code>	<code>index, smash, next, data</code>	Add type u entry to <code>mathfont</code>
<code>add_to_charm</code>	string of new charm info	Add new charm into to <code>mathfont</code>
<code>parse_charm</code>	string of new charm info	Split string, validate inputs
<code>empty</code>	none	Does nothing
<code>glyph_info</code>	character subtable	Return height, width, depth, italic
<code>make_a_commands</code>	<code>index, offset</code>	Return virtual font commands
<code>make_a_table</code>	<code>index, charm data, fontdata</code>	Make new character table for type a
<code>make_e_commands</code>	<code>index, scale factors</code>	Return virtual font commands
<code>make_e_table</code>	<code>index, charm data, fontdata</code>	Make new character table for type e
<code>make_hex_value</code>	integer	Return hexadecimal string
<code>make_u_commands</code>	<code>index, offset</code>	Return virtual font commands
<code>make_u_table</code>	<code>index, charm data, fontdata</code>	Make new character table for type u
<code>modify_e_base</code>	<code>index, offset</code>	Modify base glyph for type e
<code>smash_glyph</code>	<code>index, fontdata</code>	Return table for smashed character
<code>adjust_font</code>	<code>fontdata</code>	Call callbacks
<code>apply_charm_info</code>	<code>fontdata</code>	Change character metrics in fontdata
<code>get_font_name</code>	<code>fontdata</code>	Return font name
<code>info</code>	<code>string</code>	Writes a message in the log file
<code>math_constants</code>	<code>fontdata</code>	Creates a MathConstants table
<code>set_nomath_false</code>	<code>fontdata</code>	Set top-level font specs for math

least nicer than they would otherwise.

```
1404 \ifM@adjust@font
1405 \mathnolimitsmode=4\relax
```

We need some error messages. We change the catcode of `\` to 12 in order to use it freely as a Lua escape character. We change `\~` to catcode 0 to define the macros.

```
1406 \bgroup
1407   \catcode`\~=0

1433     to do, try adding asterisks to your \\CharmLine\n%
1434     or line in your \\CharmFile.\n"}}
```

The user inputs charm information at the `\TeX` level. We define the macros `\CharmLine` that interfaces with `mathfont:add_to_charm` directly and `\CharmFile` that reads lines from a file and individually feeds them to `\CharmLine`. For `\CharmLine`, we check that the argument contains no `"` or `\` symbols because that could mess up the Lua parsing.

```
\CharmLine 1435 \protected\def\CharmLine#1{%
```

```

1436 \begingroup
1437 \edef\@tempa{#1}
1438 \edef\@tempa{\detokenize\expandafter{\@tempa}}
1439 \@expandtwoargs\in@{"}{\@tempa}

```

If #1 contains a ", we issue an error. The error help message is different depending on whether the \CharmLine came from a call to \CharmFile or not, which we check with \ifM@fromCharmFile.

```

1440 \ifin@ % is " in #1?
1441   \ifM@fromCharmFile
1442     \M@ForbiddenCharmFile{"}
1443   \else
1444     \M@ForbiddenCharmLine{"}
1445   \fi
1446 \else
1447   \@expandtwoargs\in@{\backslashchar}{\@tempa}
1448   \ifin@ % is backslash in #1?
1449     \ifM@fromCharmFile
1450       \M@ForbiddenCharmFile{\backslashchar}
1451     \else
1452       \M@ForbiddenCharmLine{\backslashchar}
1453     \fi
1454   \else

```

If #1 does not contain a quotation mark or escape char, we feed it to `mathfont:add_to_charm` as a string.

```

1455   \directlua{mathfont:add_to_charm("\@tempa")}
1456   \fi
1457 \fi
1458 \endgroup

```

The argument of \CharmFile should be a valid filename, and we open it in \M@Charm. The \M@fromCharmFiletrue command sets the boolean for an open charm file to true. This command and the corresponding false command are global because of how the kernel defines \newif. We can't check \ifeof\M@Charm because during processing of the last line from \M@Charm, we are at the end of the file even though it is still open.

```

1459 \protected\def\CharmFile#1{%
1460   \begingroup
1461   \M@fromCharmFiletrue
1462   \immediate\openin\M@Charm{#1}

```

The macro \@next will read a line in #1, feed it to \CharmLine, and call itself if the file has more lines.

```

1463 \def\@next{%
1464   \read\M@Charm to \tempa
1465   \CharmLine\@tempa
1466   \ifeof\M@Charm\else % if file has more lines?
1467     \expandafter\@next
1468   \fi}

```

Call `\@next`, close the file, and end the group.

```

1469 \@next
1470 \immediate\closein\M@Charm
1471 \M@fromCharmFilefalse
1472 \endgroup}

```

This concludes the TeX-based portion of font adjustments. The rest of this section and the next two sections are the Lua code that adapts a text font for math mode. First, we create the `mathfont` table.

```

1473 \directlua{
1474 mathfont = {}

```

Each character whose metrics we want to change will have one of three types: `a` for alphabet, `e` for extensible, and `u` for (other) unicode. (We don't really create extensibles—type `e` means any character that we need artificially larger sizes for.) We begin with type `a`. The `index` is the base-10 unicode value of the character that we will later modify, and `next` is the base-10 unicode value of the slot we will use to store the modified glyph. The `data` variable is a table with 4 entries that stores sizing information and information regarding accent placement. We divide the information by 1000 as is standard in TeX.

```

1475 function mathfont:new_type_a(index, next, data)
1476   self[index] = {}
1477   self[index].type = "a"
1478   self[index].next = next
1479   self[index].left_stretch = data[1] / 1000
1480   self[index].right_stretch = data[2] / 1000
1481   self[index].top_accent_stretch = data[3] / 1000
1482   self[index].bot_accent_stretch = data[4] / 1000
1483 end

```

Initializing type `e` characters is more complicated. The `index` argument is the base-10 unicode value of the character we will modify. The `smash` value is a unicode slot where we will store a smashed version of the glyph with no height, depth, or width, which we need to scale the glyph correctly. We use `next` and `data` to add large variants of characters to the font. Specifically, `next` is a table of unicode slots where we will add larger versions of the character with unicode value `index`, and `data` stores the sizing information.

```
1484 function mathfont:new_type_e(index, smash, next, data)
```

We determine the number of larger variants v from the length of `next`, and we store that number in `total_variants`.

```
1485   local v = \string# next
1486   self[index] = {}
1487   self[index].type = "e"
1488   self[index].smash = smash
1489   self[index].next = next
1490   self[index].total_variants = v
1491   self[index].data = {}
```

We expect `data` to have $2v + 2$ entries, which we consider in pairs. The i th pair (i.e. entries i and $i + 1$ of `data`) encodes the horizontal and vertical scale factors for the i th large variant, and the final two entries determine top and bottom accent placement. We store each pair as a two-element table in the larger table `mathfont[index].data`, and we use `x` and `y` as the keys for the horizontal and vertical stretch. Again we divide both scale factors by 1000.

```
1492   for i = 1, v, 1 do
1493     self[index].data[i] = {}
1494     self[index].data[i].x = data[2*i-1] / 1000
1495     self[index].data[i].y = data[2*i] / 1000
1496   end
1497   self[index].top_accent_stretch = data[2*v+1] / 1000
1498   self[index].bot_accent_stretch = data[2*v+2] / 1000
1499 end
```

The type `u` characters are simplest. We need to specify the unicode index in the first argument. The second function argument is a table with two entries that stores accent information.

```
1500 function mathfont:new_type_u(index, data)
1501   self[index] = {}
1502   self[index].type = "u"
1503   self[index].top_accent_stretch = data[1] / 1000
1504   self[index].bot_accent_stretch = data[2] / 1000
1505 end
```

Interim processing. We let the user edit resizing and accent information for the characters in `mathfont`. The function `mathfont.parse_charm` parses and validates the user's input, and the function `mathfont:add_to_charm` incorporates the user's information into the tables already in `mathfont`. The `mathfont:add_to_charm` function expects a single string of integers, floats, or asterisks separated by spaces or commas and immediately passes it to `parse_charm`. Our first task is to split the string into components, and we

store the results in `split_string`. The dummy variable `i` keeps track of the number of entries currently in `split_string`.

```
1506 function mathfont.parse_charm(charm_input)
1507   local split_string = {}
1508   local charm_string = charm_input
1509   local temp_string = ""
1510   local i = 1
```

We loop through `charm_string` as long as it contains a comma or space. At each iteration, we remove the portion of `charm_string` preceding the first comma or space and append it to `split_string` as a separate entry.

```
1511   while string.find(charm_string, " ") or
1512     string.find(charm_string, ",") do
1513     local length = string.len(charm_string)
1514     local first_space = string.find(charm_string, " ") or length
1515     local first_comma = string.find(charm_string, ",") or length
```

We store the location of the first comma or space in `sep`.

```
1516   local sep = first_space
1517   if first_comma < first_space then
1518     sep = first_comma
1519   end
```

Now split `charm_string` at `sep`. We store the portion before `sep` in `temp_string`, and the portion after `sep` becomes the new `charm_string`.

```
1520   temp_string = string.sub(charm_string, 1, sep-1)
1521   charm_string = string.sub(charm_string, sep+1)
```

If `temp_string` is not empty, we store it in position `i` in `split_string`, then increment `i` by 1. If `temp_string` does not contain a number or asterisk, we raise an error.

```
1522   if temp_string \noexpand~= "" then
1523     if tonumber(temp_string) then % if a number, append it
1524       split_string[i] = tonumber(temp_string)
1525       i = i+1
1526     elseif temp_string == "*" then % if asterisk, append it
1527       split_string[i] = temp_string
1528       i = i+1
1529     else % if neither, raise error
1530       error(\M@number@ssert)
1531     end
1532   end
1533 end
```

After iteratinf the splitting procedure, we have a final portion of `charm_string` with no commas or spaces, and we perform the same check as on `temp_string` above.

```
1534 temp_string = charm_string
1535 if temp_string \noexpand~= "" then
1536   if tonumber(temp_string) then % if a number, append number
1537     split_string[i] = tonumber(temp_string)
1538   elseif temp_string == "*" then % if asterisk, append asterisk
1539     split_string[i] = temp_string
1540   else % if neither, raise error
1541     error(\M@number@ssert)
1542   end
1543 end
```

The last step is to make sure that the first entry of `split_string` is a valid unicode index. We know that the first entry is either an asterisk or a number, and we make sure it is not an asterisk.

```
1544 local index = split_string[1]
1545 if index == "*" then
1546   error(\M@index@ssert)
1547 end
```

The last check is to make sure the entry is (1) an integer and not a float; (2) nonnegative; and (3) less than 1,114,111, the maximum unicode entry. We round the entry down by subtracting the decimal portion, and the result will be equal to the original entry if and only if we begin with an integer. We perform the three checks inside an `assert` and issue an error if any of them fail, and if `split_string` is valid, we return it to `mathfont:add_to_charm`.

```
1548 local rounded = index - (index \@percentchar 1) % round down
1549 local max = 1114111
1550 assert(index == rounded and
1551       index >= 0      and
1552       index <= max, \M@index@ssert)
1553 return split_string
1554 end
```

We feed the user's charm information directly to `mathfont:add_to_charm`, which first calls `parse_charm` to parse the input and then modifies `mathfont` accordingly. After being parsed, we store the user's input in `charm_metrics`. The `index` is the base-10 unicode value of the character whose information we want to modify, and the `number_of_entries` is the length of `charm_metrics`.

```
1555 function mathfont:add_to_charm(charm_string)
1556   local charm_metrics = self.parse_charm(charm_string)
```

```
1557 local index = charm_metrics[1]
1558 local number_of_entries = \string# charm_metrics
```

If `mathfont` does not already have an entry for the unicode character `index`, we create an entry with type `u`.

```
1559 if not self[index] then
1560   self:new_type_u(index, {0, 0})
1561 end
```

Handling the user's input depends on the type of entry `index`. The basic procedure is to first check that the input has enough entries and, if yes, to overwrite the numbers stored in `mathfont`'s corresponding subtable with the new information. If the user included an asterisk, we do nothing to that metric value. For type `a`, we need four entries besides the `index`. The first two will overwrite the left and right offset, and the last two overwrite accent placement.

```
1562 if self[index].type == "a" then
1563   local entries_needed = 5
1564   assert(number_of_entries >= entries_needed, \M@entries@assert)
1565   if charm_metrics[2] \noexpand~= "*" then
1566     self[index].left_stretch = charm_metrics[2] / 1000
1567   end
1568   if charm_metrics[3] \noexpand~= "*" then
1569     self[index].right_stretch = charm_metrics[3] / 1000
1570   end
1571   if charm_metrics[4] \noexpand~= "*" then
1572     self[index].top_accent_stretch = charm_metrics[4] / 1000
1573   end
1574   if charm_metrics[5] \noexpand~= "*" then
1575     self[index].bot_accent_stretch = charm_metrics[5] / 1000
1576   end
```

Type `e` is more complicated. The number of entries in the `charm_metrics` must be at least $2 * \text{total_variants} + 3$. We loop through the information and, for each i th pair of charm values, set those numbers to be the horizontal and vertical stretch information for the i th variant. We handle type `r` in the same way.

```
1577 elseif self[index].type == "e" then
1578   local tot_variants = self[index].total_variants
1579   local entries_needed = 2 * tot_variants + 3
1580   assert(number_of_entries >= entries_needed, \M@entries@assert)
1581   for i = 1, tot_variants, 1 do
1582     if charm_metrics[2*i] \noexpand~= "*" then
1583       self[index].data[i].x = charm_metrics[2*i] / 1000
```

```

1584     end
1585     if charm_metrics[2*i+1] \noexpand~= "*" then
1586         self[index].data[i].y = charm_metrics[2*i+1] / 1000
1587     end
1588 end

```

The final two entries for type e or r are the accent information.

```

1589     if charm_metrics[2 * tot_variants + 2] \noexpand~= "*" then
1590         self[index].top_accent_stretch =
1591             charm_metrics[2 * tot_variants + 2] / 1000
1592     end
1593     if charm_metrics[2 * tot_variants + 3] \noexpand~= "*" then
1594         self[index].bot_accent_stretch =
1595             charm_metrics[2 * tot_variants + 3] / 1000
1596     end

```

Again the information for type u is the simplest. We need two values besides the index, one for the top accent and one for the bottom accent.

```

1597 elseif self[index].type == "u" then
1598     local entries_needed = 3
1599     assert(number_of_entries >= entries_needed, \M@entries@assert)
1600     if charm_metrics[2] \noexpand~= "*" then
1601         self[index].top_accent_stretch = charm_metrics[2] / 1000
1602     end
1603     if charm_metrics[3] \noexpand~= "*" then
1604         self[index].bot_accent_stretch = charm_metrics[3] / 1000
1605     end
1606 end
1607 end

```

We end this section with three general-purpose Lua functions. The first function, `make_hex_value`, accepts a nonnegative integer and returns its hexadecimal representation as a string. The result will go in the variable `hex_string`. We handle the cases of 0 and 1 manually.

```

1608 function mathfont.make_hex_value(integer)
1609     if integer == 0 then
1610         return "0000"
1611     end
1612     if integer == 1 then
1613         return "0001"
1614     end
1615     local hex_digits = "0123456789ABCDEF" % for reference
1616     local hex_string = ""
1617     local curr_val = integer

```

```
1618 local remainder = 0
```

Otherwise, we find the number of hexadecimal digits that we will need to represent the `integer`. We loop through the integers and stop when we reach the first power of 16 that is greater than `integer`.

```
1619 local i = 0
1620 while 16^i <= curr_val do
1621   i = i+1
1622 end
```

Once we know how many hex digits we will need, we subtract off successively smaller powers of 16. Our dummy variable `j` starts as the greatest power of 16 less than or equal to `integer`, and we divide by 16^j . The quotient becomes the first hexadecimal digit, and we repeat the process with the remainder and a smaller value of `j`. The final result is the hexadecimal representation of our original `integer`.

```
1623 for j = i-1, 0, -1 do
1624   remainder = curr_val \@percentchar (16^j)
1625   curr_val = (curr_val - remainder) / (16^j)
1626   hex_string = hex_string ..
1627   string.sub(hex_digits, curr_val+1, curr_val+1)
1628   curr_val = remainder
1629 end
```

If `hex_string` has fewer than 4 digits, we add enough leading 0's to bring it to 4 digits.

```
1630 if \string# hex_string < 4 then
1631   for i = \string# hex_string, 4, 1 do
1632     hex_string = "0" .. hex_string
1633   end
1634 end
1635 return hex_string
1636 end
```

The `glyph_info` function does exactly what it sounds like. It accepts a character table from a font and returns the width, height, depth, and italic correction values.

```
1637 function mathfont.glyph_info(char)
1638   local glyph_width = char.width or 0
1639   local glyph_height = char.height or 0
1640   local glyph_depth = char.depth or 0
1641   local glyph_italic = char.italic or 0
1642   return glyph_width, glyph_height, glyph_depth, glyph_italic
1643 end
```

The `:smash_glyph` function returns a character table that will produce a smashed version of the unicode character with value `index`. The character has no width, height, or depth and typesets the glyph virtually using a `char` font command.

```
1644 function mathfont:smash_glyph(index, fontdata)
1645   local smash_table = {}
1646   smash_table.width = 0
1647   smash_table.height = 0
1648   smash_table.depth = 0
1649   smash_table.commands = {{"char", index}}
1650   return smash_table
1651 end
```

An empty function that does nothing. Used later for creating callbacks.

```
1652 function mathfont.empty(arg)
1653 end
```

10 Adjust Fonts: Changes

This section contains the Lua functions that actually modify the font during loading. The three functions `set_nomath_false`, `math_constants`, and `apply_charm_info` do most of the heavy lifting, and we set them as the default behavior for three callbacks. In total, `mathfont` defines six different callbacks and calls them inside the function `adjust_font`—see table 4 for a list. Each callback accepts a `fontdata` object as an argument and returns nothing. You can use these callbacks to change `mathfont`'s default modifications or to modify a `fontdata` object before or after `mathfont` looks at it. Be aware that if you add a function to any of the `disable_nomath`, `add_math_constants`, or `fix_character_metrics` callbacks, `LuaTeX` will not call the default `mathfont` function associated with the callback anymore. In other words, do not mess with these three callbacks unless you are duplicating the functionality of the corresponding “Default Behavior” function from table 4.

We begin with the functions that modify character subtables in the font table, and in all cases, we return a new character table (or set of character tables in the case of type `e`) that we insert into the font object. For types `a` and `e`, we code the table from scratch, and for type `u`, we add information to the character tables that already exist in the font object. The three functions for assembling character tables take three arguments. The `index` argument is the unicode index of the base character that the function is modifying. The `charm_data` argument is the subtable in `mathfont` of charm information that

corresponds to `index`, and the `fontdata` argument is a font object. We will pull information from `charm_data` and `fontdata` to assemble the new table.

We will incorporate five categories of information into our new character tables: glyph dimensions, unicode values, accent placement dimensions, virtual font commands, and math kerning. For type `a`, we increase the original horizontal glyph dimensions based on charm information, and for type `e`, we increase the width by horizontal scale factors and the height and depth by vertical scale factors. Accent placement dimensions come from charm information. For types `a` and `e`, we return a character table that will become a virtual character in the font, and we need to include commands to typeset certain base characters. For type `e`, we also create the large variants through `pdf` commands that stretch the base glyphs.

The type `a` commands include one command to move to the right by some offset and one command to typeset the base glyph.

```
1654 function mathfont.make_a_commands(index, offset)
1655   local c_1 = {"right", offset}
1656   local c_2 = {"char", index}
1657   return {c_1, c_2}
1658 end
```

The `:make_a_table` returns a character table for type `a` characters. We store the information to return in the variable `a_table` and the character subtable in `char`. The `slant` is the font's `slant` parameter and is used for calculating accent placement.

```
1659 function mathfont:make_a_table(index, charm_data, fontdata)
1660   local a_table = {}
1661   local char = fontdata.characters[index] or {}
1662   local slant = fontdata.parameters.slant / 65536 or 0
```

The `left_stretch` and `right_stretch` values come from charm data and tell us how much extra space to add to the left and right sides of the character.

Table 4: Callbacks Created by `mathfont`

Callback Name	Default Behavior
" <code>mathfont.inspect_font</code> "	None
" <code>mathfont.pre_adjust</code> "	None
" <code>mathfont.disable_nomath</code> "	<code>mathfont.set_nomath_false</code>
" <code>mathfont.add_math_constants</code> "	<code>mathfont.math_constants</code>
" <code>mathfont.fix_character_metrics</code> "	<code>mathfont.apply_charm_info</code>
" <code>mathfont.post_adjust</code> "	None

Importantly, these values are additive.

```
1663 local left_stretch = charm_data.left_stretch
1664 local right_stretch = charm_data.right_stretch
1665 local width, height, depth, italic = self.glyph_info(char)
```

Incorporate the italic correction into the character width.

```
1666 width = width + italic
```

The new width is $1 + \text{left_stretch} + \text{right_stretch}$ times the original width. The horizontal offset that appears in the commands is the `left_stretch` portion of the new width.

```
1667 local offset = width * left_stretch
1668 a_table.width = width * (1 + left_stretch + right_stretch)
1669 a_table.height = height
1670 a_table.depth = depth
1671 a_table.italic = italic
1672 a_table.unicode = index
```

The `tounicode` entry is a hexadecimal string that encodes the unicode value of the base character.

```
1673 a_table.tounicode = self.make_hex_value(index)
```

We specify accent placement information by including `top_accent` and `bot_accent` entries in the `a_table`. We determine placement by setting the `top_accent` to be a base value plus a distance determined by the charm data and similarly for `bot_accent`. We imagine dividing up the character's bounding box as follows: (1) some rectangular portion of the left and right areas of the bounding box is empty space added according to `left_stretch` and `right_stretch`; (2) accordingly, the glyph occupies some rectangular area in the middle of the bounding box; (3) if the font is slanted, that rectangle will actually be a parallelogram where the rectangle overhangs both slanted edges of the parallelogram in two triangles; and (4) we can determine the size of these triangles according to the `slant` font parameter. We want the base measurement for the top accent to be located in the middle of the parallelogram from step (3) previously, and we end up with

$$\begin{aligned} \text{base measurement} &= \text{left_stretch} * \text{width} \\ &\quad + 0.5 * (\text{width} - \sigma_1 * \text{height}) + \sigma_1 * \text{height}, \end{aligned}$$

where σ_1 is the `slant` parameter and `width` and `height` refer to the character in question. This equation simplifies to

$$(0.5 + \text{left_stretch}) * \text{width} + 0.5\sigma_1 * \text{height},$$

which is the formula we use for the base value of the top accent. We determine the base value of the bottom accent similarly. For the shift amount, we take the corresponding factor from the charm information and multiply it by the width of the character. Note that in all these cases, we use the `width`, not the `new_width` as our unit of measurement. This keeps the scaling of the accent placement independent of the `left_stretch` and `right_stretch` values.

```
1674 local top_base = (0.5 + left_stretch) * width +
1675   0.5 * slant * height
1676 local bot_base = (0.5 + left_stretch) * width -
1677   0.5 * slant * height
1678 local top_accent_shift = charm_data.top_accent_stretch * width
1679 local bot_accent_shift = charm_data.bot_accent_stretch * width
1680 a_table.top_accent = top_base + top_accent_shift
1681 a_table.bot_accent = bot_base + bot_accent_shift
```

Add the commands to the table.

```
1682 a_table.commands = self.make_a_commands(index, offset)
```

Because we are keeping the character's italic correction, we have superscripts and subscripts that are too far from the glyph if we leave things as is. The reason is that LuaTeX adds italic correction of the nucleus to the horizontal position of superscripts when it formats exponents. Accordingly we want to move both superscript and subscript left by the italic correction of the nucleus, so we add a mathkern table to the character. A mathkern table contains up to four subtables, one for each corner of the character. Within each subtable, we store pairs of `height` and `kern` values, where `height` means to apply `kern` to exponents at that height. In this case, we have a `kern` value of minus italic correction in the upper and lower right corners.

```
1683 a_table.mathkern = {}
1684 a_table.mathkern.top_right = {{height = 0, kern = -italic}}
1685 a_table.mathkern.bottom_right = {{height = 0, kern = -italic}}
1686 a_table.mathkern.top_left = {{height = 0, kern = 0}}
1687 a_table.mathkern.bottom_left = {{height = 0, kern = 0}}
1688 return a_table
1689 end
```

For type `e` characters, we need a function to modify the base glyph. We incorporate the italic correction into the width and add extra italic correction in the case of the integral symbol.

```
1690 function mathfont:modify_e_base(index, fontdata)
1691   local char = fontdata.characters[index] or {}
1692   local width, height, depth, italic = self.glyph_info(char)
1693   char.width = width + italic
```

We trim the bounding box on the surd if the user requests it. Some text fonts extend the bounding box of the surd past the edge of the glyph, and we trim the edge of the box according to the values of `\M@SurdHorizontalFactor` and `\M@SurdVerticalFactor`.

```
1694 if index == 8730 then
```

Now get the scale factors from the TeX side of things and scale down (or up) the height and width of the surd.

```
1695 local horizontal_scale =
1696   tex.getcount("M@SurdHorizontalFactor") / 1000
1697 local vertical_scale =
1698   tex.getcount("M@SurdVerticalFactor") / 1000
1699 char.width = horizontal_scale * char.width
1700 char.height = vertical_scale * height
1701 end
```

For the integral symbol, get the scale factor add the appropriate italic correction.

```
1702 if index == 8747 then
1703   local scale_factor =
1704     tex.getcount("M@IntegralItalicFactor") / 1000
1705   char.italic = scale_factor * width
1706 end
1707 end
```

For the `e` commands, we not only typeset a certain glyph but also instruct the `pdf` backend to scale by a horizontal and vertical factor before doing so. In this way, we artificially add larger variants of a particular base glyph. The `pdf` command sends code directly to the `pdf` backend that handles the transformation. The `q` command indicates a linear transformation of the output, and the following string contains the transformation coordinates. The `Q` command restores the original coordinate system, and because it occurs between the transformation commands, the typeset glyph from the `char` command will be enlarged according to the transformation matrix.

```
1708 function mathfont.make_e_commands(index, h_stretch, v_stretch)
1709   local c_1 = {"pdf", "origin",
1710     string.format("q \0@percentchar s 0 0 \0@percentchar s 0 0 cm",
1711       h_stretch, v_stretch)}
1712   local c_2 = {"char", index}
1713   local c_3 = {"pdf", "origin", "Q"}
1714   return {c_1, c_2, c_3}
1715 end
```

The function for type e characters returns a table with different structure because we need to create multiple characters at once. Specifically, the function returns a table with one entry for each larger variant that we want to add to the font. Many of the variables are the same as in :make_type_a. We store the base character subtable in `char` and the font's `slant` parameter in `slant`. The `tounicode` stores the hexadecimal unicode value of the base character for reference later, and `smash_index` is the index of the unicode slot that we are using to hold the smashed version of the base character.

```
1716 function mathfont:make_e_table(index, charm_data, fontdata)
1717   local e_table = {}
1718   local char = fontdata.characters[index] or {}
1719   local slant = fontdata.parameters.slant / 65536
1720   local tounicode = self.make_hex_value(index)
1721   local smash_index = charm_data.smash
1722   local width, height, depth, italic = self.glyph_info(char)
```

We will create a number of entries in `e_table` equal to the number of variants we want, which is stored in `charm_data.total_variants`. We iteratively assemble the `e_table`, and we begin the iteration by extracting the `i`th horizontal and vertical scale factors from `charm_data`. The width, height, and depth of the `i`th new character will be scalings of these values from the original character.

```
1723   for i = 1, charm_data.total_variants, 1 do
1724     local h_stretch = charm_data.data[i].x
1725     local v_stretch = charm_data.data[i].y
1726     local new_width = width * h_stretch
1727     local new_height = height * v_stretch
1728     local new_depth = depth * v_stretch
1729     local new_italic = italic * h_stretch
```

We add new character bounds to the `i`th entry of `e_table`.

```
1730   e_table[i] = {}
1731   e_table[i].width = new_width
1732   e_table[i].height = new_height
1733   e_table[i].depth = new_depth
1734   e_table[i].italic = new_italic
```

Add the unicode information.

```
1735   e_table[i].unicode = index
1736   e_table[i].tounicode = tounicode
```

We handle accent placement the same way as with type a characters.

```
1737   local base_top_accent = 0.5 * new_width +
1738         0.5 * slant * new_height
```

```

1739     local base_bot_accent = 0.5 * new_width -
1740         0.5 * slant * new_height
1741     local top_accent_shift =
1742         charm_data.top_accent_stretch * new_width
1743     local bot_accent_shift =
1744         charm_data.bot_accent_stretch * new_width
1745     e_table[i].top_accent = base_top_accent + top_accent_shift
1746     e_table[i].bot_accent = base_bot_accent + bot_accent_shift

```

Add the commands.

```

1747     e_table[i].commands =
1748         self.make_e_commands(smash_index, h_stretch, v_stretch)

```

If we aren't dealing with the last entry in the table, we need to add the character's `next` fields. The next larger variant after the `i`th character will be the `i + 1`st character, and we can extract the index from the `charm_info`.

```

1749     if i < charm_data.total_variants then
1750         e_table[i].next = charm_data.next[i+1]
1751     end
1752 end
1753 return e_table
1754 end

```

Making the `u` table is the easiest. We take the character subtable from `fontdata` as our starting point rather than assembling a new character subtable from scratch. The structure here is very similar to type `a` without the extra space from the `left_stretch` and `right_stretch`. Again, we incorporate the italic correction into the bounding box and add a negative `mathkern` to compensate.

```

1755 function mathfont:make_u_table(index, charm_data, fontdata)
1756     local u_table = fontdata.characters[index] or {}
1757     local slant = fontdata.parameters.slant / 65536 or 0
1758     local width, height, depth, italic = self.glyph_info(u_table)
1759     local new_width = width + italic
1760     u_table.width = new_width

```

We handle accents in the same way as with the other types.

```

1761     local base_top_accent = 0.5 * new_width +
1762         0.5 * slant * height
1763     local base_bot_accent = 0.5 * new_width -
1764         0.5 * slant * height
1765     local top_accent_shift =
1766         charm_data.top_accent_stretch * new_width
1767     local bot_accent_shift =
1768         charm_data.bot_accent_stretch * new_width

```

```
1769 u_table.top_accent = base_top_accent + top_accent_shift
1770 u_table.bot_accent = base_bot_accent + bot_accent_shift
```

Add a mathkern table as in the case of type a characters.

```
1771 u_table.mathkern = {}
1772 u_table.mathkern.top_right = {{height = 0, kern = -italic}}
1773 u_table.mathkern.bottom_right = {{height = 0, kern = -italic}}
1774 u_table.mathkern.top_left = {{height = 0, kern = 0}}
1775 u_table.mathkern.bottom_left = {{height = 0, kern = 0}}
1776 return u_table
1777 end
```

Before we get to the main font-changing functions, we code `make_fake_angle`, which returns a character table for the fake angle brackets. The function accepts the index of the smashed character as `index` and the index of the smashed gillement as `smash`. We form the fake angle bracket by using only the top 90% of the original glyph, and we scale it to have the same height and depth as the left parenthesis.

```
1778 function mathfont.make_fake_angle(index, smash, fontdata)
1779   local temp = {}
1780   local lparen = fontdata.characters[40] or {}
1781   local lparen_height = lparen.height or 0
1782   local lparen_depth = lparen.depth or 0
1783   local glyph = fontdata.characters[index] or {}
1784   local glyph_height = glyph.height or 0
1785   local base_height = 0.9 * glyph_height
1786   local factor = 0
1787   if glyph_height \noexpand~= 0 then
1788     factor = (lparen_height + lparen_depth) / base_height
1789   end
1790   local shift = 0.1 * glyph_height * factor + lparen_depth
1791   temp.height = lparen_height
1792   temp.depth = lparen_depth
1793   temp.width = glyph.width or 0
1794   temp.italic = glyph.italic or 0
1795   temp.top_accent = glyph.top_accent or 0.5 * temp.width
1796   temp.bot_accent = glyph.bot_accent or 0.5 * temp.width
1797   temp.commands = {
1798     {"down", shift},
1799     {"pdf", "origin",
1800      string.format("q 1 0 0 \\\@percentchar s 0 0 cm", factor)},
1801     {"char", smash},
1802     {"pdf", "origin", "Q"},
```

```

1803     {"down", -shift]}
1804   return temp
1805 end

```

We come to the main functions that modify the font. We need to accomplish three tasks, and we define separate functions for each one. First, we set the font's `nomath` entry to `false`. Second, we incorporate the modifications based on charm information into the font, i.e. set the font's character subtables using the previous functions from this section. Third, we need to add a MathConstants table. The first task is very easy.

```

1806 function mathfont.set_nomath_false(fontdata)
1807   fontdata.nomath = false
1808   fontdata.oldmath = false
1809 end

```

The second task is more involved. The basic idea is to loop through `mathfont`, and whenever we find an entry that is a subtable, we treat it as charm information that we use to modify the font object. We begin by storing the character information from the font in `chars` for easier reference later.

```

1810 function mathfont.apply_charm_info(fontdata)
1811   local chars = fontdata.characters or {}

```

Before we loop through the charm data, we need to add fake angle brackets and `\nabla` to the font. We begin with the angle brackets.

```

1812   chars[1044538] = mathfont:smash_glyph(8249, fontdata) % \lguil
1813   chars[1044539] = mathfont:smash_glyph(8250, fontdata) % \rguil
1814   chars[1044540] = mathfont:smash_glyph(171, fontdata) % \llguil
1815   chars[1044541] = mathfont:smash_glyph(187, fontdata) % \rrguil

```

Now add the characters to the font.

```

1816   chars[1044508] = mathfont.make_fake_angle(
1817     8249, 1044538, fontdata)
1818   chars[1044509] = mathfont.make_fake_angle(
1819     8250, 1044539, fontdata)
1820   chars[1044510] = mathfont.make_fake_angle(
1821     171, 1044540, fontdata)
1822   chars[1044511] = mathfont.make_fake_angle(
1823     187, 1044541, fontdata)

```

Add the nabla (inverted Delta) character to the font if it is missing.

```

1824   if not chars[8711] then
1825     chars[8710] = chars[8710] or {}
1826     chars[1044508] = mathfont:smash_glyph(8710, fontdata)
1827     chars[8711] = {}
1828     chars[8711].width = chars[8710].width or 0

```

```

1829     chars[8711].height = chars[8710].height or 0
1830     chars[8711].depth = chars[8710].depth or 0
1831     chars[8711].italic = chars[8710].italic or 0
1832     chars[8711].top_accent = chars[8710].top_accent or
1833         0.5 * chars[8711].width
1834     chars[8711].bot_accent = chars[8710].bot_accent or
1835         0.5 * chars[8711].width
1836     chars[8711].unicode = 8711
1837     chars[8711].tounicode = mathfont.make_hex_value(8711)
1838     chars[8711].commands = {
1839         {"down", -chars[8711].height},
1840         {"pdf", "origin", "q 1 0 0 -1 0 0 cm"},,
1841         {"char", 1044508},,
1842         {"pdf", "origin", "Q"},,
1843         {"down", chars[8711].height}}
1844 end

```

Perform the loop. We care about entries `info` whose type is a table.

```

1845 for index, info in pairs(mathfont) do
1846     if type(info) == "table" then

```

If the character's type is `a`, all we need to do is replace the character subtable in the font with our version.

```

1847     if info.type == "a" then
1848         chars[info.next] =
1849             mathfont:make_a_table(index, info, fontdata)

```

Again, type `e` is more complicated. This time we need to insert multiple character subtables into the font, one for the smashed version of the base glyph and others corresponding to the large variants that we create using the `:make_e_table` function from above. We also need to add `next` entries to the characters in the font linking all the variants together.

```

1850     elseif info.type == "e" then
1851         local smash = info.smash
1852         chars[index] = chars[index] or {}

```

Set the `next` entry on the current character, modify the character's dimensions to incorporate italic correction into the width, and add a smashed version of the glyph into the font.

```

1853         chars[index].next = info.next[1]
1854         mathfont:modify_e_base(index, fontdata)
1855         chars[smash] = mathfont:smash_glyph(index, fontdata)

```

The function that creates the character table for type `e` produces one character subtable for each larger variant that we want to add, so we loop through the

resulting table and add the contents to the font one at time. Each subtable goes in unicode slots that we take from the charm information, specifically the `next` table from `info`.

```
1856     local variants_table =
1857         mathfont:make_e_table(index, info, fontdata)
1858     for i = 1, info.total_variants, 1 do
1859         chars[info.next[i]] = variants_table[i]
1860     end
```

We deal with type u in the same way as we do type a.

```
1861     elseif info.type == "u" then
1862         chars[index] =
1863             mathfont:make_u_table(index, info, fontdata)
1864     end
1865 end
1866 end
1867 end
```

The `populate_math_constants` function is even more complicated because we need to add a full MathConstants table to the font object, which has some fifty parameters that we need to set. To keep things simple, we set the font parameters in terms of traditional TeX \fontdimen parameters. Besides the eight essential parameters found in all fonts, TeX traditionally uses some fifteen extra parameters to typeset math formulas. To preserve whatever structure may already exist in the font object, we do not override any MathConstants that the font already contains.

```
1868 function mathfont.math_constants(fontdata)
1869   fontdata.MathConstants = fontdata.MathConstants or {}
```

First evaluate the dimensions from the font object that we will use in determining other math parameter values. The `A_height` is the height of the capital “A” character, and the `y_depth` is the depth of the lower-case “y” character. Both will be 0 if the font does not have the correct character.

```
1870 local size = fontdata.size or 0
1871 local ex = fontdata.parameters.x_height or 0
1872 local em = fontdata.parameters.quad or 0
1873 local A_height = 0
1874 local y_depth = 0
1875 if fontdata.characters[65] then
1876   A_height = fontdata.characters[65].height or 0 % A
1877 end
1878 if fontdata.characters[121] then
1879   y_depth = fontdata.characters[121].depth or 0 % y
1880 end
```

We begin by setting the axis height and default rule thickness. We need to start with these parameters because we will use them to calculate other constants. We set both values to 0 initially and then change them.

```
1881 local axis = 0
1882 local rule_thickness = 0
```

Set the default rule thickness. If the font already has a value set for the parameter `FractionRuleThickness`, we take that as the default rule thickness, and otherwise we set it to be $1/18$ of the font size times the adjustment factor from `\M@RuleThicknessFactor`, which is the value of that `\count` divided by 1000.

```
1883 local dim = "FractionRuleThickness"
1884 if not fontdata.MathConstants[dim] then
1885   local scale_factor =
1886     tex.getcount("M@RuleThicknessFactor") / 1000
1887   rule_thickness = (size / 18) * scale_factor
1888   fontdata.MathConstants[dim] = rule_thickness
1889 else
1890   rule_thickness = fontdata.MathConstants[dim]
1891 end
```

If the font does not have `AxisHeight` already set, we set the axis to be the height of a minus sign (character 45). As a fallback, we set the axis to 0.8ex if the font does not have a character in unicode slot 45. If the font has an `AxisHeight`, we take that value as the `axis`.

```
1892 local dim = "AxisHeight"
1893 if fontdata.MathConstants[dim] then
1894   axis = fontdata.MathConstants[dim]
1895 else
1896   if fontdata.characters[45] then
1897     axis = fontdata.characters[45].height - 0.5 * rule_thickness
1898   else
1899     axis = 0.8 * ex
1900   end
1901   fontdata.MathConstants[dim] = axis
1902 end
```

Apart from the axis height and rule thickness, we can group the traditional mathematics `\fontdimen` parameters into three categories: four for large operators, five for fractions, and six for superscripts and subscripts. (OpenType math does not use the fifth large-operator parameter ξ_{13} and the seventh script parameter σ_{14} .) We define variables with the same names as their traditional references from Appendix G in the *TEXBook*. I have taken the design approach

of using twice the rule height as a standard minimum clearance, and I am assuming that script styles are roughly 70% as large as text and display styles. We begin with the parameters for large operators.

The parameter ξ_9 is the minimum clearance between the top of a large operator and the limit above it, and we set it to be twice the rule thickness. Before ensuring that the bottom of the upper limit is at least ξ_9 away from the operator character, TeX attempts to position the baseline of the limit at ξ_{10} distance above the operator character, and we set ξ_{10} to be slightly larger than ξ_9 . If the upper limit has no descender, TeX will raise its baseline by ξ_{10} , and if it has a descender, TeX will position the bottom of the descender to be ξ_9 above the operator, which in practice means it will be higher than limits without descenders. This approach balances the desire for consistency in whitespace with the desire for consistency in baseline height. Similarly, we set the minimum clearance ξ_{11} for the lower limit to be equal to the attempted clearance for the upper limit, and the attempted clearance ξ_{12} for the lower limit will be the minimum clearance plus the average of the \scriptfont x-height and \scriptfont A-height.

```
1903 local xi_9 = 2 * rule_thickness      % top limit min clearance
1904 local xi_10 = xi_9 + 0.35 * y_depth % bottom limit try placement
1905 local xi_11 = xi_10                  % top limit min clearance
1906 local xi_12 = xi_10 + 0.35 * (A_height + ex) % bottom attempt
```

Our general approach for \displaystyle fractions is to place the baseline of the numerator numerator at a distance above the fraction rule of 1.5 times the rule height plus descender depth plus a small extra space. The minimum clearance will be the rule height, so we expect the numerator to strictly exceed the minimum clearance in most situations. Doing so produces consistent baselines of numerators and gives our value for σ_8 , the attempted height of the numerator in \displaystyle fractions. For smaller styles, we use a single rule height as clearance, so we add $0.5 * rule_thickness + y_depth$ scaled down by 0.7 to the rule thickness. The minimum clearance for numerator and denominator are separate OpenType parameters, and we set them later. The extra 0.1 A-height in the attempted clearance relative to the minimum clearance appears because we measure attempted clearance from the axis, whereas we measure minimum clearance from the top or bottom of the fraction rule.

```
1907 local sigma_8 = axis + 1.5 * rule_thickness + y_depth +
1908     0.1 * A_height
1909 local sigma_9 = (axis + 1.35 * rule_thickness + 0.7 * y_depth +
1910     0.07 * A_height)
1911 local sigma_10 = sigma_9
```

Our approach in the denominators is the same except that we add half the descender depth to the minimum clearance. This creates extra space below the fraction rule so that the typographical color above the rule matches that below the rule when the numerator contains descenders.

```
1912 local sigma_11 = (-axis + 1.5 * rule_thickness +
1913   0.5 * y_depth + 1.1 * A_height)
1914 local sigma_12 = (-axis + 1.35 * rule_thickness +
1915   0.35 * y_depth + 0.77 * A_height)
```

For superscripts we think in terms of the top of the superscript. We raise the baseline of the superscript by the desired height of the superscript top minus the `\scriptfont A-height`. Choosing $1.3 * \text{A_height}$ for regular styles and $1.2 * \text{A_height}$ for cramped styles was a design choice that worked well. The attempted drop for subscripts is one-fifth the A-height or slightly more than the y-depth, whichever is greater. This way the subscript baseline is slightly lower than any descenders, and for fonts without descenders, we still clearly lower the subscript. Setting σ_{18} and σ_{19} was another design choice that worked well.

```
1916 local sigma_13 = 0.6 * A_height % attempted superscript height
1917 local sigma_15 = 0.5 * A_height % attempt for cramped scripts
1918 local sigma_16 = 1.1 * y_depth % attempted subscript lower
1919 if sigma_16 < 0.2 * A_height then
1920   sigma_16 = 0.2 * A_height
1921 end
1922 local sigma_17 = sigma_16          % sigma_16 when superscript
1923 local sigma_18 = 0.5 * A_height % superscript lower for boxed
1924 local sigma_19 = 0.1 * A_height % subscript lower for boxed
```

The MathConstants themselves come from the unicode equivalents of the traditional `TEX \fontdimen` parameters where appropriate. Where not appropriate, I made design choices as indicated. Setting the next three parameters was purely a design choice.

```
1925 local dim = "DisplayOperatorMinHeight"
1926 if not fontdata.MathConstants[dim] then
1927   fontdata.MathConstants[dim] = 1.8 * A_height
1928 end
1929 local dim = "FractionDelimiterDisplayStyleSize"
1930 if not fontdata.MathConstants[dim] then
1931   fontdata.MathConstants[dim] = 2 * size
1932 end
1933 local dim = "FractionDelimiterSize"
1934 if not fontdata.MathConstants[dim] then
```

```

1935     fontdata.MathConstants[dim] = 1.3 * size
1936   end
1937 local dim = "FractionDenominatorDisplayStyleShiftDown"
1938 if not fontdata.MathConstants[dim] then
1939   fontdata.MathConstants[dim] = sigma_11
1940 end
1941 local dim = "FractionDenominatorShiftDown"
1942 if not fontdata.MathConstants[dim] then
1943   fontdata.MathConstants[dim] = sigma_12
1944 end

```

We set the minimum clearance for the numerator to be twice the rule height in `\displaystyle` and the rule height in other styles. Our approach in setting the attempted height of the numerator (σ_8 and σ_9) was to add the minimum clearance plus the descender depth plus a small extra space, so in general, we do not expect the numerator to run into the minimum clearance. For the denominator, we do the same thing except add half the descender depth to the clearance, which balances the amount of color above and below the fraction rule and is similar to what we did for the lower limits on big operators when we set ξ_{11} larger than ξ_9 .

```

1945 local dim = "FractionDenominatorDisplayStyleGapMin"
1946 if not fontdata.MathConstants[dim] then
1947   fontdata.MathConstants[dim] = rule_thickness + 0.5 * y_depth
1948 end
1949 local dim = "FractionDenominatorGapMin"
1950 if not fontdata.MathConstants[dim] then
1951   fontdata.MathConstants[dim] = rule_thickness + 0.35 * y_depth
1952 end
1953 local dim = "FractionNumeratorDisplayStyleShiftUp"
1954 if not fontdata.MathConstants[dim] then
1955   fontdata.MathConstants[dim] = sigma_8
1956 end
1957 local dim = "FractionNumeratorShiftUp"
1958 if not fontdata.MathConstants[dim] then
1959   fontdata.MathConstants[dim] = sigma_9
1960 end
1961 local dim = "FractionNumeratorDisplayStyleGapMin"
1962 if not fontdata.MathConstants[dim] then
1963   fontdata.MathConstants[dim] = rule_thickness
1964 end
1965 local dim = "FractionNumeratorGapMin"
1966 if not fontdata.MathConstants[dim] then

```

```

1967     fontdata.MathConstants[dim] = rule_thickness
1968 end

```

The `SkewedFractionHorizontalGap` and `SkewedFractionVerticalGap` take the values that LuaTeX would set for a traditional TeX font.

```

1969 local dim = "SkewedFractionHorizontalGap"
1970 if not fontdata.MathConstants[dim] then
1971   fontdata.MathConstants[dim] = 0.5 * em
1972 end
1973 local dim = "SkewedFractionVerticalGap"
1974 if not fontdata.MathConstants[dim] then
1975   fontdata.MathConstants[dim] = ex
1976 end

```

The `UpperLimit` and `LowerLimit` dimensions correspond exactly to traditional TeX math `\fontdimen` parameters.

```

1977 local dim = "UpperLimitBaselineRiseMin"
1978 if not fontdata.MathConstants[dim] then
1979   fontdata.MathConstants[dim] = xi_11
1980 end
1981 local dim = "UpperLimitGapMin"
1982 if not fontdata.MathConstants[dim] then
1983   fontdata.MathConstants[dim] = xi_9
1984 end
1985 local dim = "LowerLimitBaselineDropMin"
1986 if not fontdata.MathConstants[dim] then
1987   fontdata.MathConstants[dim] = xi_12
1988 end
1989 local dim = "LowerLimitGapMin"
1990 if not fontdata.MathConstants[dim] then
1991   fontdata.MathConstants[dim] = xi_10
1992 end

```

Traditional TeX doesn't have stack objects, but they are meant to be similar to large operators, so we set the same parameters.

```

1993 local dim = "StretchStackGapBelowMin"
1994 if not fontdata.MathConstants[dim] then
1995   fontdata.MathConstants[dim] = xi_10
1996 end
1997 local dim = "StretchStackTopShiftUp"
1998 if not fontdata.MathConstants[dim] then
1999   fontdata.MathConstants[dim] = xi_11
2000 end
2001 local dim = "StretchStackGapAboveMin"

```

```

2002 if not fontdata.MathConstants[dim] then
2003   fontdata.MathConstants[dim] = xi_9
2004 end
2005 local dim = "StretchStackBottomShiftDown"
2006 if not fontdata.MathConstants[dim] then
2007   fontdata.MathConstants[dim] = xi_12
2008 end

```

For the three `Overbar` parameters, we take the approach that the bar itself should be as thick as the rule height. The gap will be twice the rule height, and the extra clearance will be a single rule height.

```

2009 local dim = "OverbarExtraAscender"
2010 if not fontdata.MathConstants[dim] then
2011   fontdata.MathConstants[dim] = rule_thickness
2012 end
2013 local dim = "OverbarRuleThickness"
2014 if not fontdata.MathConstants[dim] then
2015   fontdata.MathConstants[dim] = rule_thickness
2016 end
2017 local dim = "OverbarVerticalGap"
2018 if not fontdata.MathConstants[dim] then
2019   fontdata.MathConstants[dim] = 2 * rule_thickness
2020 end

```

For the radical sign, we take the same approach as with the `Overbar` parameters. We insert one rule thickness of extra space above the radical symbol and two rule thickness of extra space under it. For `\textstyle` and smaller, we reduce the space to a single rule height.

```

2021 local dim = "RadicalExtraAscender"
2022 if not fontdata.MathConstants[dim] then
2023   fontdata.MathConstants[dim] = rule_thickness
2024 end
2025 local dim = "RadicalRuleThickness"
2026 if not fontdata.MathConstants[dim] then
2027   fontdata.MathConstants[dim] = rule_thickness
2028 end
2029 local dim = "RadicalDisplayStyleVerticalGap"
2030 if not fontdata.MathConstants[dim] then
2031   fontdata.MathConstants[dim] = 2 * rule_thickness
2032 end
2033 local dim = "RadicalVerticalGap"
2034 if not fontdata.MathConstants[dim] then
2035   fontdata.MathConstants[dim] = rule_thickness

```

```
2036 end
```

The final three `Radical` parameters aren't used if we handle degree placement at the macro level rather than at the font level. We set them to the default values that LuaTeX uses for traditional tfm fonts.

```
2037 local dim = "RadicalKernBeforeDegree"
2038 if not fontdata.MathConstants[dim] then
2039   fontdata.MathConstants[dim] = (5/18) * em
2040 end
2041 local dim = "RadicalKernAfterDegree"
2042 if not fontdata.MathConstants[dim] then
2043   fontdata.MathConstants[dim] = (10/18) * em
2044 end
2045 local dim = "RadicalDegreeBottomRaisePercent"
2046 if not fontdata.MathConstants[dim] then
2047   fontdata.MathConstants[dim] = 60
2048 end
```

The `SpaceAfterShift` is a design choice. Somewhat arbitrary.

```
2049 local dim = "SpaceAfterScript"
2050 if not fontdata.MathConstants[dim] then
2051   fontdata.MathConstants[dim] = 0.1 * em
2052 end
```

The `Stack` parameters come from their traditional `\fontdimen` analogues.

```
2053 local dim = "StackBottomDisplayStyleShiftDown"
2054 if not fontdata.MathConstants[dim] then
2055   fontdata.MathConstants[dim] = sigma_11
2056 end
2057 local dim = "StackBottomShiftDown"
2058 if not fontdata.MathConstants[dim] then
2059   fontdata.MathConstants[dim] = sigma_12
2060 end
2061 local dim = "StackTopDisplayStyleShiftUp"
2062 if not fontdata.MathConstants[dim] then
2063   fontdata.MathConstants[dim] = sigma_8
2064 end
2065 local dim = "StackTopShiftUp"
2066 if not fontdata.MathConstants[dim] then
2067   fontdata.MathConstants[dim] = sigma_10
2068 end
```

Traditionally TeX uses an internal method rather than a parameter to determine the minimum distance between two boxes in an `\atop` stack. We set the minimum distance to be one rule thickness plus the combined minimum clear-

ance for numerators and denominators in fractions. For `\displaystyle`, that gives us

```
rule_thickness+(2*rule_thickness)+(2*rule_thickness+0.5*y_depth)
```

For smaller styles, we use single rule height values and scale down the `y_depth` by 0.7.

```
2069 local dim = "StackDisplayStyleGapMin"
2070 if not fontdata.MathConstants[dim] then
2071   fontdata.MathConstants[dim] = 5 * rule_thickness +
2072     0.5 * y_depth
2073 end
2074 local dim = "StackGapMin"
2075 if not fontdata.MathConstants[dim] then
2076   fontdata.MathConstants[dim] = 3 * rule_thickness +
2077     0.35 * y_depth
2078 end
```

With three exceptions, superscript and subscript parameters come from traditional TeX dimensions.

```
2079 local dim = "SubscriptShiftDown"
2080 if not fontdata.MathConstants[dim] then
2081   fontdata.MathConstants[dim] = sigma_16
2082 end
2083 local dim = "SubscriptBaselineDropMin"
2084 if not fontdata.MathConstants[dim] then
2085   fontdata.MathConstants[dim] = sigma_19
2086 end
2087 local dim = "SubscriptShiftDownWithSuperscript"
2088 if not fontdata.MathConstants[dim] then
2089   fontdata.MathConstants[dim] = sigma_17
2090 end
```

The top of a subscript should be less than half the A-height. This is a somewhat arbitrary design choice.

```
2091 local dim = "SubscriptTopMax"
2092 if not fontdata.MathConstants[dim] then
2093   fontdata.MathConstants[dim] = 0.5 * A_height
2094 end
```

The minimum gap between superscripts and subscripts will be the height of the rule. This is less space than TeX traditionally allocates.

```
2095 local dim = "SubSuperscriptGapMin"
2096 if not fontdata.MathConstants[dim] then
```

```
2097     fontdata.MathConstants[dim] = rule_thickness
2098 end
```

We set the minimum height for the bottom of a subscript to be the height of a superscript in cramped styles minus the depth of a possible descender. Theoretically this is the lowest that any portion of a superscript should ever be if it contains only text.

```
2099 local dim = "SuperscriptBottomMin"
2100 if not fontdata.MathConstants[dim] then
2101   fontdata.MathConstants[dim] = sigma_15 - 0.7 * y_depth
2102 end
2103 local dim = "SuperscriptBaselineDropMax"
2104 if not fontdata.MathConstants[dim] then
2105   fontdata.MathConstants[dim] = sigma_18
2106 end
2107 local dim = "SuperscriptShiftUp"
2108 if not fontdata.MathConstants[dim] then
2109   fontdata.MathConstants[dim] = sigma_13
2110 end
2111 local dim = "SuperscriptShiftUpCramped"
2112 if not fontdata.MathConstants[dim] then
2113   fontdata.MathConstants[dim] = sigma_15
2114 end
```

If the superscript and subscript overlap, we choose the new position such that the baselines of subscripts are roughly consistent across subformulas. In this case, the bottom of the superscript box will rise at most to the point such that a subscript containing only text at 70% of the next-larger style will align with all similar subscripts. The top of the subscript will have approximate height $-\sigma_{16} + 0.7 * A_height$ above the baseline, so to find our desired position for the bottom of the superscript, we add the minimum clearance of a single rule thickness. Putting this parameter in terms of the subscript sizing is necessary because we don't know how large the descender will be in a given subscript.

```
2115 local dim = "SuperscriptBottomMaxWithSubscript"
2116 if not fontdata.MathConstants[dim] then
2117   fontdata.MathConstants[dim] = -sigma_16 +
2118     0.7 * A_height + rule_thickness
2119 end
```

As with the Overbar parameters, we set the extra clearance to be the rule height and the gap to be twice the rule height.

```
2120 local dim = "UnderbarExtraDescender"
2121 if not fontdata.MathConstants[dim] then
```

```

2122     fontdata.MathConstants[dim] = rule_thickness
2123 end
2124 local dim = "UnderbarRuleThickness"
2125 if not fontdata.MathConstants[dim] then
2126     fontdata.MathConstants[dim] = rule_thickness
2127 end
2128 local dim = "UnderbarVerticalGap"
2129 if not fontdata.MathConstants[dim] then
2130     fontdata.MathConstants[dim] = 2 * rule_thickness
2131 end

```

No reason not to set `MinConnectorOverlap` to 0. It doesn't matter for our purposes because `mathfont` doesn't use extensibles.

```

2132 local dim = "MinConnectorOverlap"
2133 if not fontdata.MathConstants[dim] then
2134     fontdata.MathConstants[dim] = 0
2135 end
2136 end

```

Time for callbacks! We create six of them.

```

2137 luatexbase.create_callback("mathfont.inspect_font",
2138     "simple", mathfont.empty)
2139 luatexbase.create_callback("mathfont.pre_adjust",
2140     "simple", mathfont.empty)
2141 luatexbase.create_callback("mathfont.disable_nomath",
2142     "simple", mathfont.set_nomath_false)
2143 luatexbase.create_callback("mathfont.add_math_constants",
2144     "simple", mathfont.math_constants)
2145 luatexbase.create_callback("mathfont.fix_character_metrics",
2146     "simple", mathfont.apply_charm_info)
2147 luatexbase.create_callback("mathfont.post_adjust",
2148     "simple", mathfont.empty)

```

The functions `mathfont.info` and `mathfont.get_font_name` are used for informational messaging. The first prints a message in the log file, and the second returns a font name.

```

2149 function mathfont.info(msg)
2150     texio.write_nl("log", "Package mathfont Info: " .. msg)
2151 end
2152 function mathfont.get_font_name(fontdata)
2153     return fontdata.fullname or
2154         fontdata.psname or
2155         fontdata.name or "<??>"
2156 end

```

The `adjust_font` function is what actually goes in `luaotfload.patch_font`. This function calls the six callbacks at appropriate times and writes informational messages in the log file.

```

2157 function mathfont.adjust_font(fontdata)
2158   luatexbase.call_callback("mathfont.inspect_font", fontdata)
2159   local the_font = mathfont.get_font_name(fontdata)
2160   if fontdata.nomath then
2161     mathfont.info("Adjusting font " .. the_font .. ".")
2162     luatexbase.call_callback("mathfont.pre_adjust",
2163       fontdata)
2164     luatexbase.call_callback("mathfont.disable_nomath",
2165       fontdata)
2166     luatexbase.call_callback("mathfont.add_math_constants",
2167       fontdata)
2168     luatexbase.call_callback("mathfont.fix_character_metrics",
2169       fontdata)
2170     luatexbase.call_callback("mathfont.post_adjust",
2171       fontdata)
2172   else
2173     mathfont.info("No changes made to " .. the_font .. ".")
2174   end
2175 end

```

Finally, add the processing function to `luaotfload`'s `patch_font` callback.

```

2176 luatexbase.add_to_callback("luaotfload.patch_font",
2177   mathfont.adjust_font, "mathfont.adjust_font")

```

11 Adjust Fonts: Metrics

This section contains the default charm information for the characters that `mathfont` adjusts upon loading a font. We will make new variants in the private use area of the font. Lower-case Latin letters will fill unicode slots U+FF000 through U+FF021, which are located in the Supplemental Private Use Area-A portion of the unicode table.

```

```

We add the charm information for delimiters and other resizable characters. We divide the characters into four categories depending on how we want to magnify the base glyph to create large variants: delimiters, big operators, vertical characters, and the integral sign. We automate the process by putting charm information for each category of character into a separate table and feeding the whole thing to a wrapper around :new_type_e.

```

2287 local delim_glyphs = {40, %
2288   41,      % )
2289   47,      % /
2290   91,      % [

```

The variable `smash` will keep track of the unicode index used to store the smashed version of the character.

```
2333 local smash = 1044544
```

Each category of type `e` character will have its own table of charm information with different magnification values. each table is initially empty.

```

2334 local delim_scale = {}
2335 local big_op_scale = {}

```

```
2336 local vert_scale = {}
2337 local int_scale = {}
```

Populate each table with magnification information. For every type e character we will create fifteen larger variants in the font. Delimiters stretch mostly vertically and some horizontally. Vertical characters stretch vertically only, so their horizontal scale factors are all constant. Big operators stretch the same in vertical and horizontal directions.

```
2338 for i = 1, 15, 1 do
2339   delim_scale[2*i-1] = 1000 + 100*i % delimiters - horizontal
2340   delim_scale[2*i] = 1000 + 500*i    % delimiters - vertical
2341   vert_scale[2*i-1] = 1000
2342   vert_scale[2*i] = 1000 + 500*i    % vertically scaled chars
2343   big_op_scale[2*i-1] = 1000 + 100*i % big operators - horizontal
2344   big_op_scale[2*i] = 1000 + 100*i  % big operators - vertical
```

The integral sign is particular. Visually, we would like an integral symbol that is larger than the large operators, which means that the integral sign should have no variants between the font's value of \Umathoperatorsize and the desired larger size. Accordingly, I decided it would be easiest to have large variants of the integral sign jump by large enough scale factors that the smallest variant larger than the regular size is already significantly larger than the \Umathoperatorsize setting in `populate_math_constants`. Effectively this means that the user should take the size of the integral operator as fixed and should set \Umathoperatorsize to make all other big operators the desired size.

```
2345   int_scale[2*i-1] = 1000 + 500*i    % integral sign - horizontal
2346   int_scale[2*i] = 1000 + 1500*i    % integral sign - vertical
2347 end
```

We do not modify accent placement.

```
2348 delim_scale[31] = 0
2349 delim_scale[32] = 0
2350 big_op_scale[31] = 0
2351 big_op_scale[32] = 0
2352 vert_scale[31] = 0
2353 vert_scale[32] = 0
2354 int_scale[31] = 0
2355 int_scale[32] = 0
```

The wrapper for `:new_type_e`. We feed it the index to use for the smashed base character, a list of characters to create charm information for, and a table of scaling information.

```
2356 function mathfont:add_extensible_variants(first_smash, glyph_list,
```

```

2357     scale_list)
2358   local variants = (\string# scale_list - 2) / 2
2359   local curr_smash = first_smash
2360   for i = 1, \string# glyph_list, 1 do
2361     local curr_char = glyph_list[i]

```

The `curr_slots` list will hold the base-10 unicode index values of each larger variant of the base character. We will take a number of unicode slots following the smashed character equal to the number of large variants we want to create, which we stored in `variants`.

```

2362   local curr_slots = {}
2363   for j = 1, variants, 1 do
2364     curr_slots[j] = curr_smash + j
2365   end

```

Add the charm information and increment `smash`.

```

2366   self:new_type_e(curr_char, curr_smash, curr_slots, scale_list)
2367   smash = smash + variants + 1
2368   curr_smash = smash
2369 end
2370 end

```

Add the charm information for the type e characters.

```

2371 mathfont:add_extensible_variants(smash, delim_glyphs, delim_scale)
2372 mathfont:add_extensible_variants(smash, big_op_glyphs, big_op_scale)
2373 mathfont:add_extensible_variants(smash, vert_glyphs, vert_scale)
2374 mathfont:add_extensible_variants(smash, int_glyphs, int_scale)

```

Finally, end the call to `\directlua` and balance the preceding conditional.

```

2375 }
2376 \fi % matches previous \ifM@adjust@font

Set new operator font. If `mathfont` is set to adjust fonts, we will have a problem when typesetting operators because the `\operator@font` will pull modified (lengthened) letters from the operator font. Traditional TeX addressed this problem by storing the Latin letters for math in the same encoding slots but in a different font from Computer Modern Roman and switching to Computer Modern Roman. Here we want to use the same font but different encoding slots. The macro `\M@default@latin` changes all `\Umathcodes` of Latin letters from their big (lengthened) values to their original values. Because `\operator@font` is always called inside a group, we don't have to worry about messing up any other math.

Before we start declaring symbols, specifically minus or equals signs, we have to address a minor clash with `amsmath`. That package defines `\relbar` and `\Relbar` as essentially a minus and equals sign respectively. However, those two control sequences are for making arrows, so they should come from the `arrows` font, not the `symbols` font. If the user already called `\mathfont` with the `arrows` keyword, we do nothing because `\M@arrows@set` defines `\relbar` and `\Relbar` correctly. If not, we make these two control sequences be the current minus and equals sign (before the font changes in `\M@symbols@set`) because that's as good a choice as any, and we prevent `amsmath` from changing them to the `symbols` font. Users or package authors who want to modify `\relbar` or `\Relbar` should change `\@relbar` or `\@Relbar` respectively.

```

Now a bit of housekeeping. We redefine \#, \%, and \& as \protected macros that expand to previously declared \mathhash, etc. commands in math mode and retain their standard \char definitions otherwise. Other commands that function in both math and horizontal modes such as \S or \dag also use this

technique. Then we define macros `\cong` and `\simeq` if the user hasn't called `\mathfont` with `extsymbols`.

```

The commands `\relbar` and `\Relbar` produce a smashed minus and an equals sign respectively. They are helper control sequences that \LaTeX uses to create other arrows. We have a small issue with `amsmath` because in \XeTeX and \LuaTeX , `amsmath` defines `\relbar` and `\Relbar` in terms of the `\Umathcodes` of the minus and equals signs respectively. That is a good approach in general, but it doesn't work when a package like `mathfont` allows users to pick different fonts for symbols and arrows. We really want `\relbar` and `\Relbar` to come from the `arrows` font, so our approach is to define the control sequences now and then redefine `\AtBeginDocument` if needed.

```

3334  \let\@relbar\@undefined
3335  \let\@Relbar\@undefined
3336  \CDMS{\@relbar}{\mathbin}{\M@arrows@font}{2212}
3337  \CDMS{\@Relbar}{\mathrel}{\M@arrows@font}{3D}

```

```
3338 \protected\gdef\relbar{\mathrel{\mathpalette\mathsm@sh\@relbar}}
3339 \protected\gdef\Relbar{\@Relbar}
```

We redefine stuff if `amsmath` gets loaded after `mathfont`.

```
3340 \@ifpackageloaded{amsmath}
3341   {\relax}{%
3342     \global\let\@@relbar\relbar
3343     \global\let\@@Relbar\Relbar
3344     \AtBeginDocument{\@ifpackageloaded{amsmath}{%
3345       \global\let\relbar\@@relbar
3346       \global\let\Relbar\@@Relbar
3347     }{\relax}}}}
```

Set blackboard bold letters and numbers. The alphanumeric keywords work a bit differently from the other font-setting commands. We define `\mathbb` here, which takes a single argument and is essentially a wrapper around `\M@bb@mathcodes`. That command changes the `\Umathcodes` of letters to the unicode hex values of corresponding blackboard-bold characters, and throughout, `\M@bb@num` stores the family number of the symbol font for the `bb` character class. In the definition of `\mathbb`, we use `\begingroup` and `\endgroup` to avoid creating unexpected atoms. The other alphanumeric keywords work similarly.

```

And that's everything!

Version History

New features and updates with each version. Listed in no particular order.

1.1b	July 2018	1.6	December 2019
—initial release		—separated implementation and user documentation	
1.2	August 2018	—created <code>mathfont_heading.tex</code>	
—minor bug fix for <code>\mathfrak</code>		—created	
—eliminated redundant batchfile		<code>mathfont_doc_patch.tex</code> for use with the index	
1.3	January 2019	—changed <code>mathfont_greek.pdf</code> to <code>mathfont_symbol_list.pdf</code>	
—added <code>symbols</code> keyword		—eliminated	
—created <code>mathfont_example.pdf</code>		<code>mathfont_example.pdf</code>	
—corrected the description of the <code>mathastext</code> package		—eliminated <code>operators</code> package option	
—font-change <code>\message</code> added to <code>\mathfont</code>		—eliminated <code>packages</code> package option	
1.4	April 2019	—font name can be package option	
— <code>\setfont</code> command added		—added Hebrew and Cyrillic characters	
— <code>\mathfont</code> optional argument can parse spaces		—separated ancient Greek from modern Greek characters	
— <code>no-operators</code> now default package optional argument		—created new keywords: <code>extsymbols</code> , <code>delimiters</code> , <code>arrows</code> , <code>diacritics</code> , <code>bigops</code> , <code>extbigops</code>	
—added <code>\comma</code> command		—improved messaging	
—new fancy fatal error message		—improved internal code for local font-change commands	
—improved messaging for <code>\mathfont</code>		—improved space parsing for the optional argument of <code>\mathfont</code>	
—internal command <code>\mathpound</code> changed to <code>\mathhash</code>		—bug fix for <code>\#</code> , etc. commands	
—added a missing #1 after <code>\char`\"</code> in the example code		—bad input for <code>\mathbb</code> , etc. now gives a warning	
—redefining <code>"</code> in the user guide		—improved error checking for <code>\newmathrm</code> , etc. commands	
1.5	April 2019	— <code>\mathfont</code> now ignores bad options (on top of issuing an error)	
—separated <code>\increment</code> and <code>\Delta</code>		—internal commands now begin with <code>\M@...</code>	
—version history added			
—initial off-the-shelf use insert added			

- added Easter Egg!
- improved indexing
- `mathfont.dtx` renamed as `mathfont_code.dtx`
- `\newmathbold` renamed as `\newmathbf`
- default local font changes now use `\updefault`, etc.
- added fatal error for missing `fontspec`
- fatal errors result in `\endinput` rather than `\@@end`

2.0 December 2021

Big Change: Font adjustments for LuaTeX: new glyph boundaries for Latin letters in math mode, resizable delimiters, big operators, MathConstants table based on font metrics.

- added `\CharmLine` and `\CharmFile`
- added `\mathconstantsfont`
- certain dimensions in equations are now adjustable when typesetting with LuaTeX
- added `adjust` and `no-adjust` package options
- automatic generation of `ind` file
- fixed symbols for `\leftharpoonup`, `\leftharpoondown`, and fraktur R
- cleaned up internal code and documentation
- font names for `\mathfont` stored to avoid multiple symbol font declarations with the same font
- more information about nfss family names stored and provided

- added option `empty`
- raised upper bound on `\DeclareSymbolFont` to 256
- reintroduced `mathfont_example.tex` with different contents
- changed several symbol-commands to `\protected` rather than robust macros
- many user-level commands are now `\protected`
- `\updefault` changed to `\shapedefault`
- eliminated `\catcode` change for space characters when scanning optional argument of `\mathfont`
- improved messaging for `\mathfont`
- removed dependence on `fontspec` and added internal font-loader
- switched `\epsilon` and `\varepsilon`
- switched `\phi` and `\varphi`
- changed / to produce a solidus in math mode and added `\fracslash`
- removed `\restoremathinternals` from the user guide
- `\setfont` now sets `\mathrm`, etc.
- added `\newmathsc`, other math alphabet commands for small caps

2.1 November 2022

- `\mathbb`, etc. commands change `\Umathcodes` of letters instead of `\M@{bb,etc.}@{letter}` commands
- removed warnings about non-letter contents of `\mathbb`, etc.

<ul style="list-style-type: none"> —fonts loaded twice, once with default settings (for text) and once in base mode (for math) —<code>\mathconstantsfont</code> accepts “upright” or “italic” as optional argument <p>2.2 December 2022</p> <ul style="list-style-type: none"> —changed the easter egg text —updated patch for <code>\DeclareSymbolFont</code> to work with changes to the kernel (eliminated <code>\M@p@tch@decl@re</code> error message) —calling Plain T_EX on <code>mathfont_code.dtx</code> produces sty file and no pdf file <p>2.2a December 2022</p> <ul style="list-style-type: none"> —bug fix for <code>\mathconstantsfont</code> —bug fix for <code>\M@check@int</code> —added <code>doc2</code> option to <code>ltxdoc</code> in <code>mathfont_code.dtx</code> <p>2.2b August 2023</p> <ul style="list-style-type: none"> —minor changes to code and documentation —<code>\ng</code> now works in math (as not greater than symbol) and text (as pronunciation symbol) <p>2.3 September 2023</p> <ul style="list-style-type: none"> —solidus and <code>\fractionslash</code> are <code>\mathord</code> instead of <code>\mathbin</code> —removed <code>\mathfont{fontspec}</code> functionality —redesigned font-loader —added package options <code>default-loader</code> and <code>fontspec-loader</code> 	<p>2.4 April 2025</p> <ul style="list-style-type: none"> —<code>\colon</code> is <code>\mathpunct</code> instead of <code>\mathord</code> —moved <code>\relbar</code> and <code>\Relbar</code> to <code>arrows</code> —reformatted <code>mathfont_code.pdf</code> —made compatible with <code>\mathbb</code>, etc. commands from other packages —renamed <code>set_nomath_true</code> to <code>set_nomath_false</code> —improved messaging —<code>\AtBeginDocument</code> —removed deprecated package options, <code>\newmathbold</code>, <code>\restoremathinternals</code> —more Easter egg messages <p>2.4a June 2025</p> <ul style="list-style-type: none"> —bug fix involving nil value and <code>the_font</code> —changed underscores in file names to hyphens
---	---

Index

Upright entries refer to lines in the code, and italic entries indicate pages in the document. **Bold** means a definition.
